Regional Roundup: Coast-to-coast growth

29 October 2026

Key takeaways

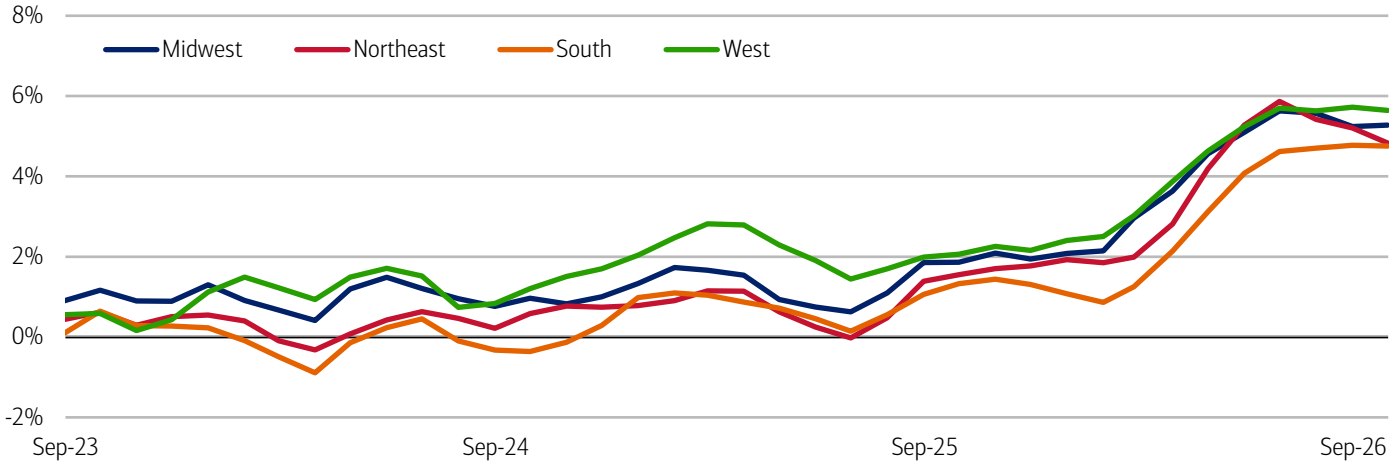

- Bank of America aggregated credit and debit card spending per household is growing at healthy rates across the country. Discretionary spending growth has improved markedly relative to the last two years. While the West has led recently and the South has lagged somewhat, no region appears to be experiencing a meaningful consumer slowdown.
- The South has seen softer discretionary retail spending, particularly in home-related durable goods categories. However, the region continues to post the strongest after-tax wage growth and has been the largest contributor to growth in new business applications nationwide.
- Business formation is occurring across a wide range of industries, with professional services, retail, healthcare, construction and hospitality all accounting for meaningful shares of new business applications. While entrepreneurial activity is broad-based across industries nationwide, industry revenue mixes vary considerably by region.

Spending growth is solid across all regions

Spending growth was strongest in the West in September, while spending growth lagged in the Northeast and South, though not by much. Total credit and debit card spending per household increased around 5.6% year-over-year (YoY) in the West, outpacing other regions by less than a percentage point, according to Bank of America aggregated card data (Exhibit 1). All regions also experienced major improvements in spending growth compared to last year, increasing by over three percentage points in every region.

Spending growth in the Northeast peaked at around 6% YoY in June but remained a solid 4.8% YoY in September. The slowest growth was in the South, though spending was still up nearly 4.8% YoY.

Exhibit 1: Spending growth has mostly improved since the start of the year across all regions
Total card spending per household by US Census region (three-month moving average, YoY%)

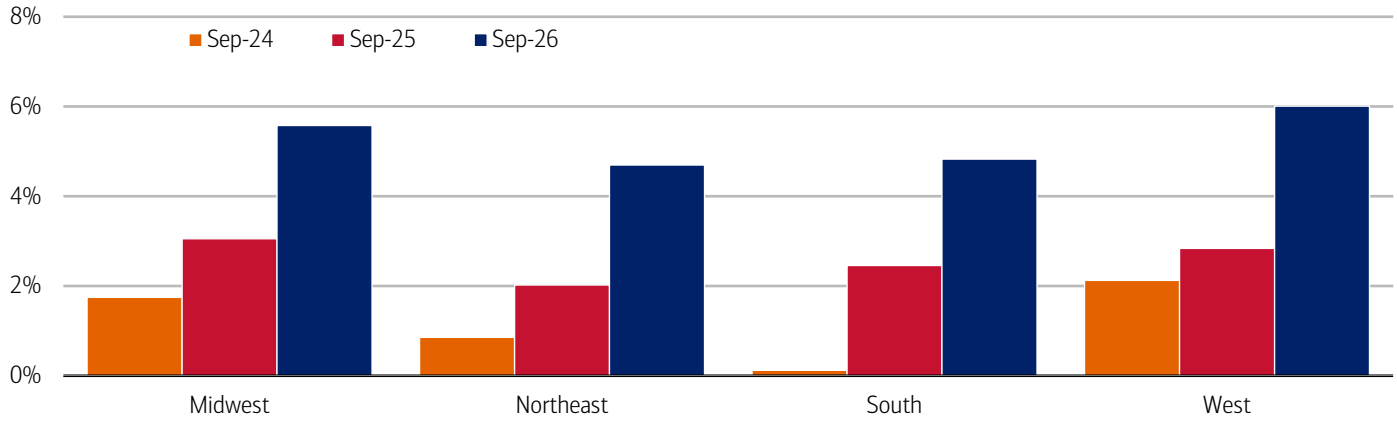

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Discretionary spending growth was also somewhat weaker in the Northeast and South than in the Midwest and West (Exhibit 2). However, these two regions have also seen the most improvement in “nice-to-have” spending over the past two years. And here spending was also up around 4.8% YoY in both regions, still a very healthy rate of growth.

Exhibit 2: Discretionary spending growth has improved across all regions compared to the past two years
Discretionary card spending per household by US Census region (three-month moving average, YoY%)

Source: Bank of America internal data
Note: Discretionary spending is all card spending minus gas, groceries and utilities.

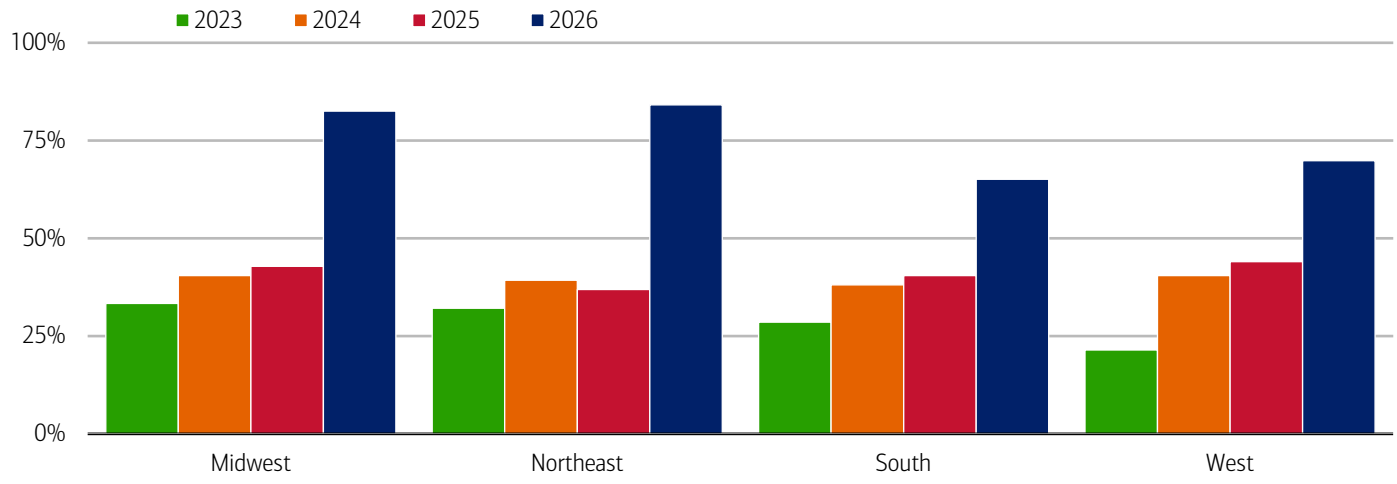

BANK OF AMERICA INSTITUTE

Durables spending is weighing on discretionary retail spending in the South

One of the key themes from September in the overall spending data was a broadening in spending growth, particularly in "more discretionary" retail categories like clothing, electronics, building materials and non-store/miscellaneous retailers (read more in Consumer Checkpoint: Strength in numbers). Bank of America card data shows that this improvement is occurring across all regions.

However, the South lags, though this is mostly due to declines in spending on home-related durables in, for instance, home improvement stores and at furniture retailers. In our view, this could reflect some slowdown in domestic migration to the Sun Belt and a corresponding easing in home/moving-related spending (read more in On the move: Renovation over relocation?)

Exhibit 3: The Midwest and Northeast have seen a higher share of discretionary retail categories with spending growth when compared to the South and West
Diffusion index across "more discretionary" retail categories by spending across US Census regions (monthly, %)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

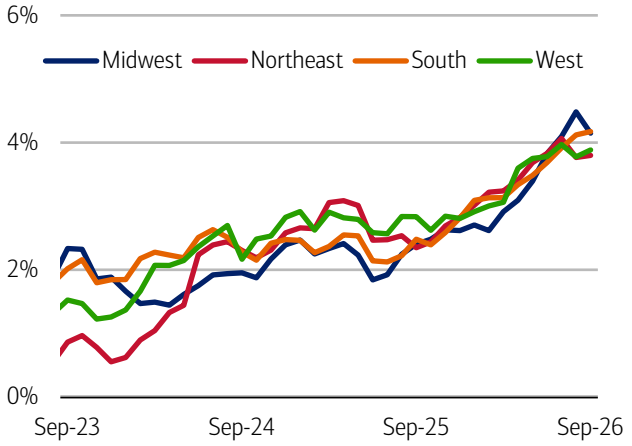

The South leads in after-tax wage and business application growth

One reason we are not overly concerned about consumer spending in the South is the strength of after-tax wage growth in the region. Bank of America deposit data suggests that after-tax wage growth was strongest there, though only by a slim margin, up nearly 4.2% YoY, just ahead of households in the Midwest, and outpacing the West and Northeast by less than half a percentage point (Exhibit 4).

Beyond wage income, business ownership offers another potential channel for wealth accumulation. The South has been the primary contributor to overall US growth in new business applications so far in 2026, according to US Census Bureau data (Exhibit 5).

While historically only a small share of these applications is likely to become a business employing workers, this surge in applications points to a potential pipeline of entrepreneurial activity. For businesses that become established and profitable, ownership can provide a pathway to wealth through retained earnings and the accumulation of business equity. Still, the extent of that opportunity depends on businesses' survival, profitability and financing needs (read more in Business Checkpoint: Looking into logistics).

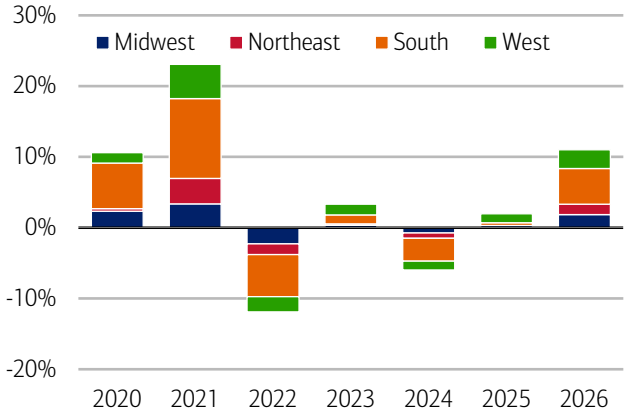

Exhibit 4: After-tax wages are accelerating across all regions, though growth was strongest in the South and Midwest
After-tax wage and salary growth by US Census region (three-month moving average, YoY%, seasonally adjusted (SA))

Source: US Census Bureau
Note: 2026 is YTD through September

BANK OF AMERICA INSTITUTE

Business application growth is widespread across regions and industries

Looking at 2026 business applications by industry, entrepreneurial activity spans multiple industry groupings (Exhibit 6). Professional, scientific, technical and other services account for the largest share, followed by retail trade and the grouping comprising healthcare, education services and the arts. Additionally, businesses provide a significant source of income for US households. In fact, business revenues accounted for nearly 14% of total pre-tax income, according to the US Census' 2025 Survey of Consumer Finances.

Exhibit 6: Professional, scientific, technical and other services industries comprise a significant share of business formation
Share of new business applications by industry groupings (annual, 2026 year-to-date, %)

Source: US Census Bureau
Note: All other includes manufacturing, mining, utilities, wholesale trade, management of companies and enterprises as well as agriculture.

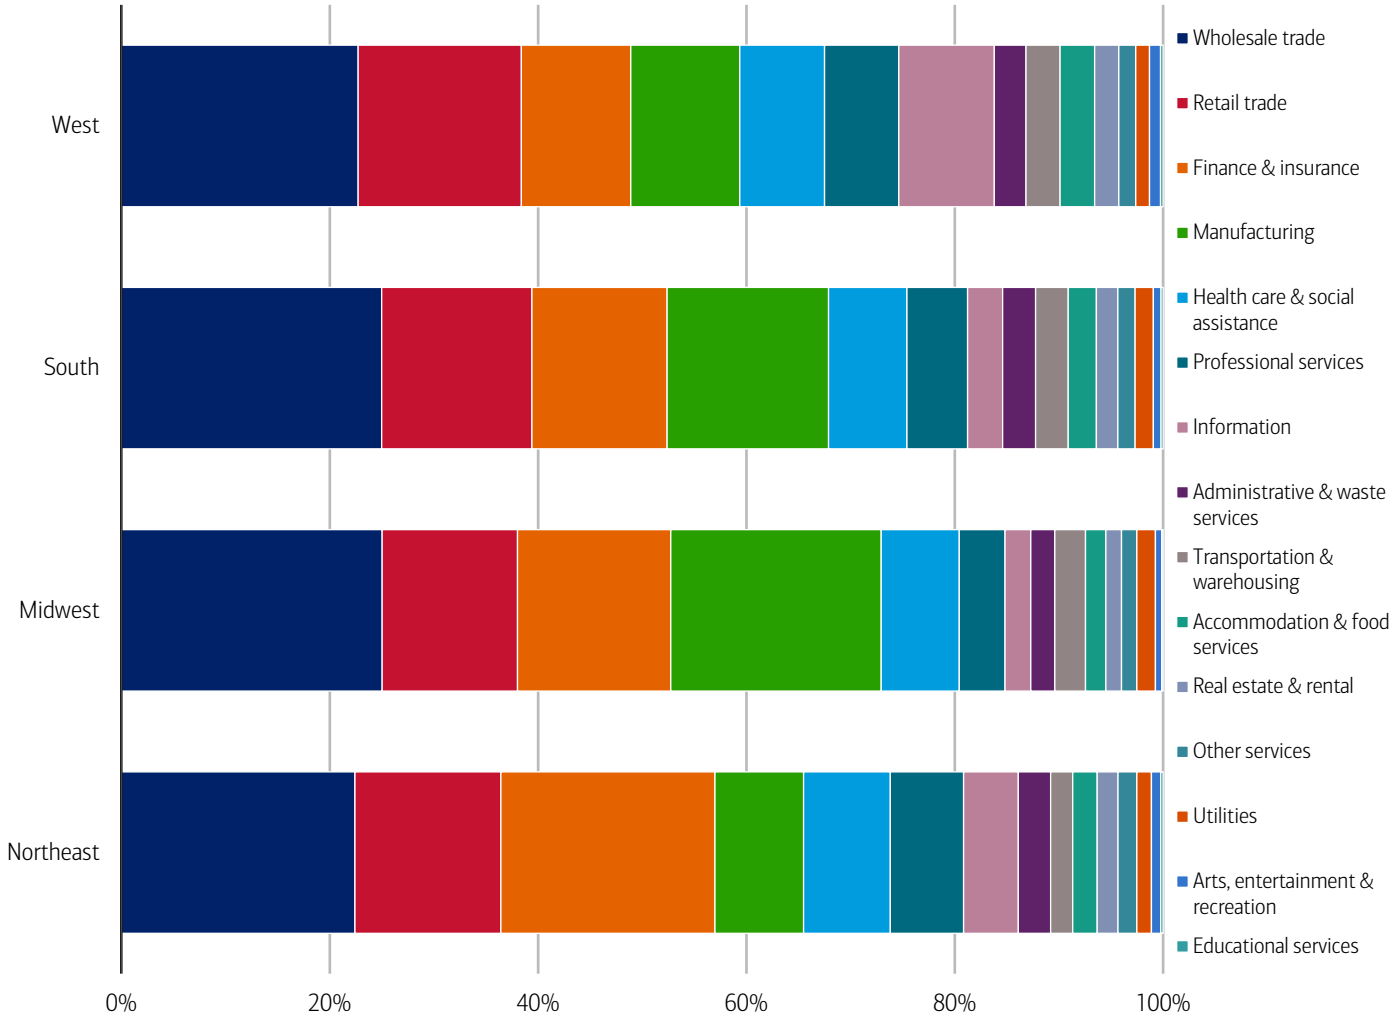

BANK OF AMERICA INSTITUTE

Combined, this suggests that potential pathways to business ownership extend not only across various households (read more on generational shifts in entrepreneurship in July's A new generation of business formation) but also across many industries, rather than a single sector.

While business applications show the breadth of prospective entrepreneurial activity nationwide, the industry composition of existing business revenue offers a regional lens on business activity. Exhibit 7 shows how revenue was distributed across industries within regions according to the 2024 Annual Integrated Economic Survey from the US Census Bureau, highlighting the extent to which regional economies are concentrated in particular sectors.

Although wholesale trade was the sector with the largest share of revenue in each region in the US, there is notable variance in economic activity from business revenues across the country. For example, finance and insurance accounted for more than 20% of revenue in the Northeast, whereas it's about half that in the West. Also, manufacturing was only 8.5% of revenue in the Northeast, and more than 20% in the Midwest. Overall, the data shows a dynamic national business landscape, with broad entrepreneurial activity but distinct regional differences in the industries generating revenue.

Exhibit 7: Wholesale trade was the sector with the largest share of revenue in each region in the US
Share of revenue by industry by region in 2024 (%)

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend includes total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

Any household consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level. Whenever median household savings and checking balances are quoted, the data is based on a fixed cohort of households that had a consumer deposit account (checking and/or savings account) for all months from January 2019 through the most current month of data shown.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards is excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs. Value grocers is defined using a combination of MCC code and proprietary methods.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Any reference to card spending per household on gasoline includes all purchases at gasoline stations and might include purchases of non-gas items.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

COLA comfort for older consumers?

27 October 2026

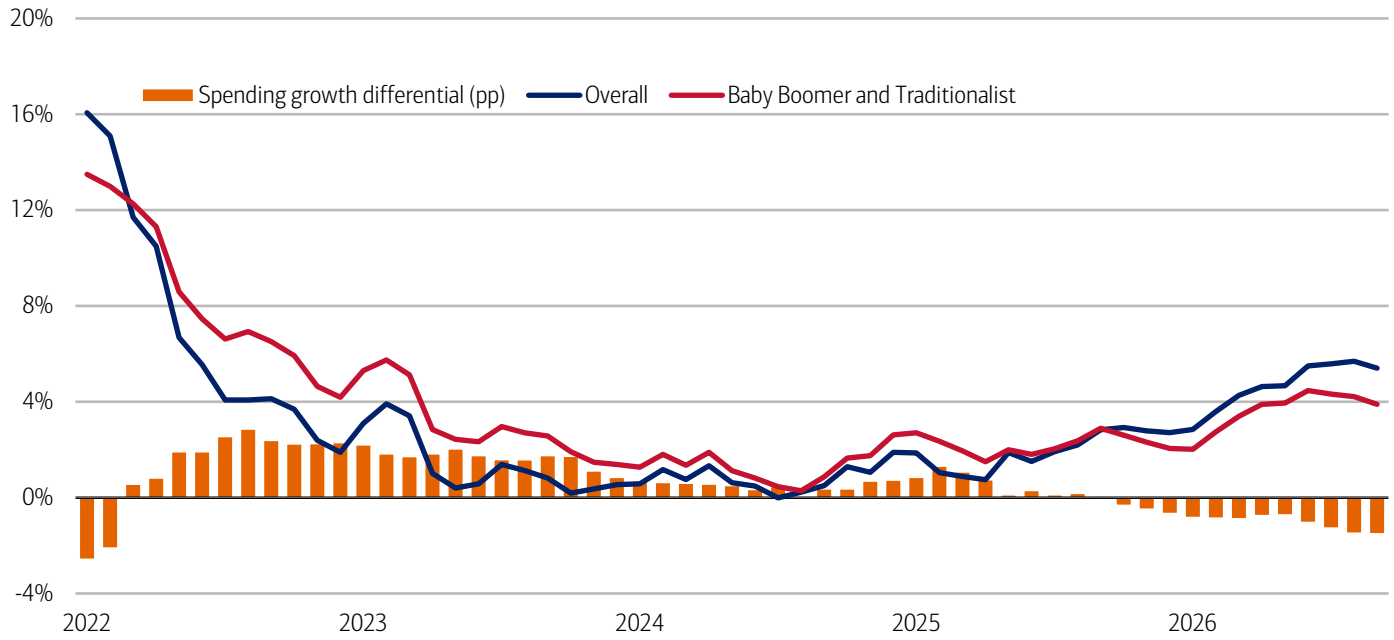

Key takeaways

- Older generations' spending growth has lagged other cohorts over the last year in Bank of America aggregated credit and debit card data, despite sizeable wealth gains. This likely partly reflects the highly uneven distribution of wealth among older households, limiting the extent to which rising wealth supports spending across the cohort.
- More recently, stronger consumer spending appears to be primarily a labor-income story. However, older households are less exposed to accelerating wage growth. In addition, large differences in their income sources help explain the considerable variation in spending among this cohort.
- The recently announced 3.6% Social Security cost-of-living adjustment could provide a meaningful boost in 2027. If inflation moderates as expected, benefit increases may outpace price growth, supporting older households' purchasing power and potentially narrowing their spending gap with other generations.

Older generations' spending growth has lagged

While total credit and debit card spending per household has picked up in 2026 in Bank of America internal data, a notable laggard has been the spending growth of older generations (Baby Boomers and Traditionalists). For around a year, discretionary spending growth for these older generations has been lower than that of overall households. This is in stark contrast to 2022-2023, when they were significantly outstripping overall household spending growth (Exhibit 1).

Exhibit 1: Discretionary spending growth has been slower among older (Baby Boomer and Traditionalist) households despite wealth effects
Total credit and debit card spending per household on discretionary categories by older generations and overall (three-month average, % YoY)

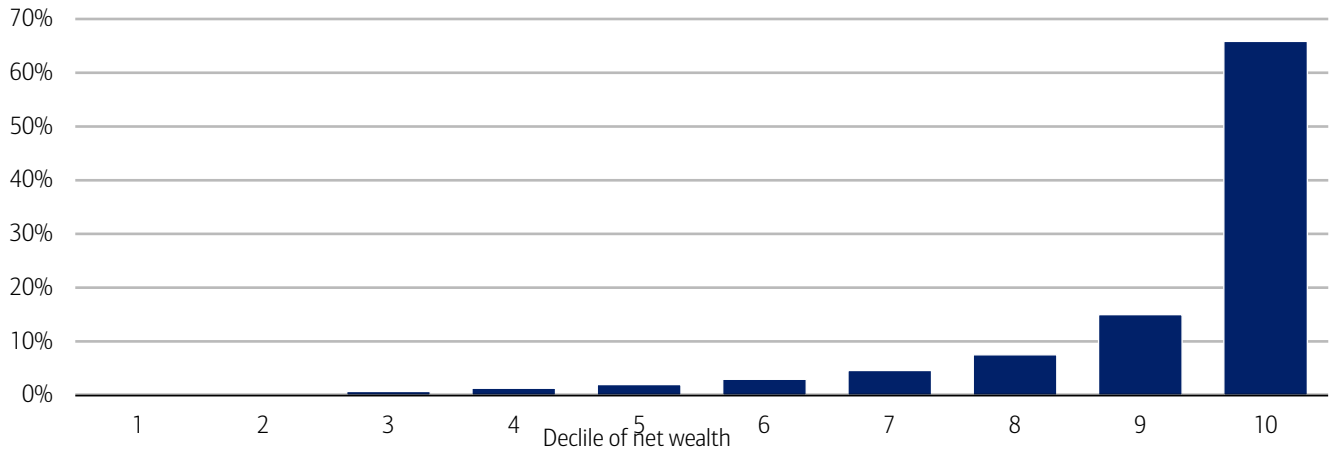

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

On one level, this observation seems surprising given that in our piece on the older consumer we noted that a large and growing proportion of net worth is held by older cohorts (read: Entering the age of the older consumer). So what's going on? One explanation is that wealth is very unevenly distributed even within the older cohort. Exhibit 2 uses the latest Federal Reserve (2025) Survey of Consumer Finances to illustrate that, across households older than 65 years of age, around two-thirds of net wealth is held by the wealthiest 10% of households. As a result, wealth gains from rising stock markets may not trickle too far down the wealth distribution of older consumers.

Exhibit 2: The wealth distribution for older households is very skewed
Distribution of net wealth for households over 65 years old (%)

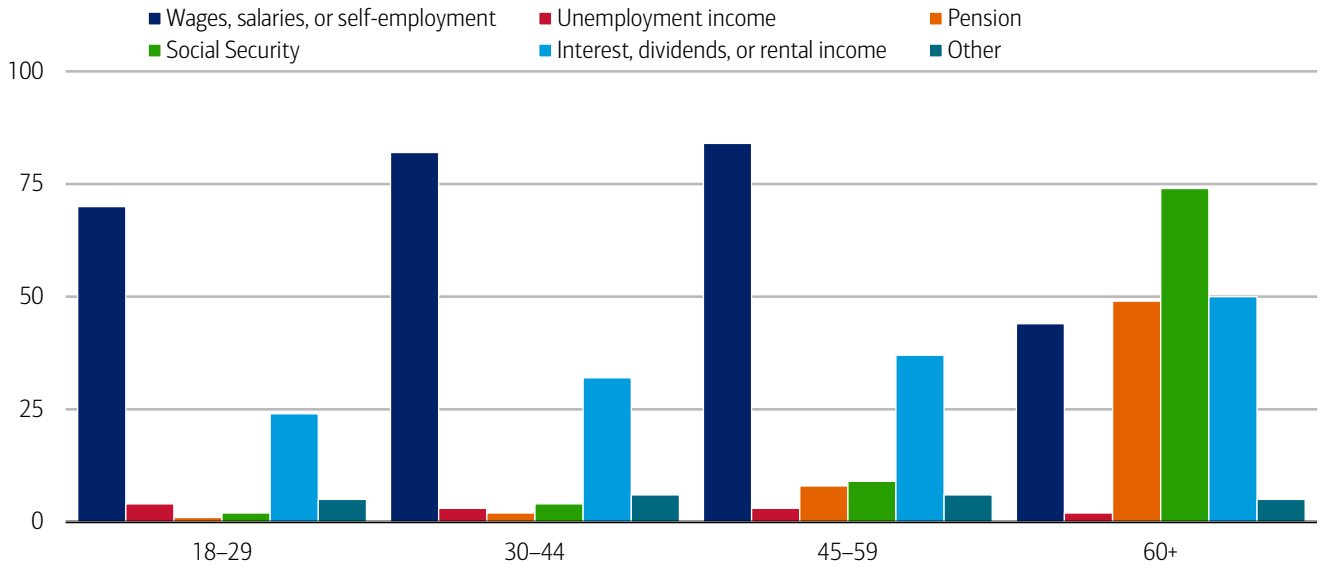

Source: Federal Reserve Board of Governors (2025 Survey of Consumer Finances)

BANK OF AMERICA INSTITUTE

Income and spending become more diverse and unequal with age

Another important part of the story is that the rise in overall spending growth over the past year appears to be supported by labor market strength as well as rising wealth. The October Consumer Checkpoint described how a pickup in after-tax wage growth among lower- and middle-income households was likely a key factor driving a recovery in these cohorts' spending growth (read: Consumer Checkpoint: Strength in numbers). As households age, their income sources become more diverse (Exhibit 3), which means older generations will likely benefit less from this pickup in wage growth.

Exhibit 3: As households age their sources of income become more diverse
Sources of income by age (%)

Source: Federal Reserve Board of Governors (2025 Survey of Household Economics and Decision making)

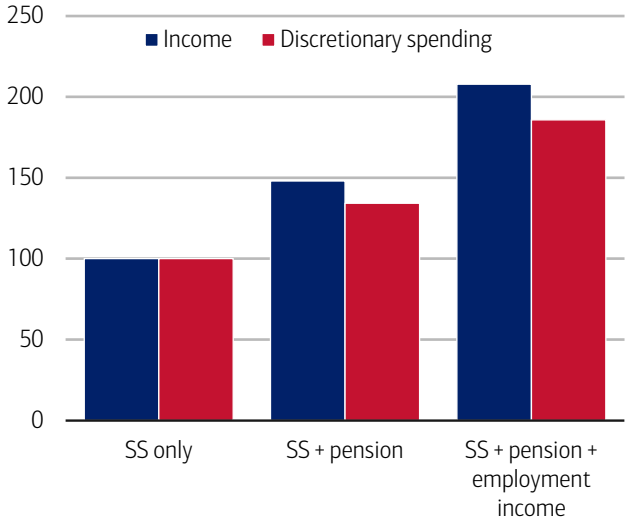

BANK OF AMERICA INSTITUTE

The greater diversity in income sources among older households helps explain the wide dispersion in their total incomes and spending. For example, using Bank of America internal data, Exhibit 4 shows that households over age 62 that rely solely on

Social Security have average income and discretionary spending levels close to half those of households that also draw income from both pensions and employment. Consistent with this, discretionary spending is distributed more unevenly among older generations by income than it is across all households (Exhibit 5).

Exhibit 4: There is considerable diversity in income and spending across older households…

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

And, interestingly, the latest Bank of America Market Landscape Insights Study shows that retirees are least confident in an improvement in their finances compared to those in work or unemployed over the next six months (Exhibit 6). Again, this may reflect the lower exposure of many retirees to the labor market, with many on relatively fixed income sources.

Exhibit 6: Retirees expect their finances to be little changed over the next six months

Source: Bank of America Market Landscape Insights Study (October 2026)

BANK OF AMERICA INSTITUTE

The 2027 COLA may offer some respite

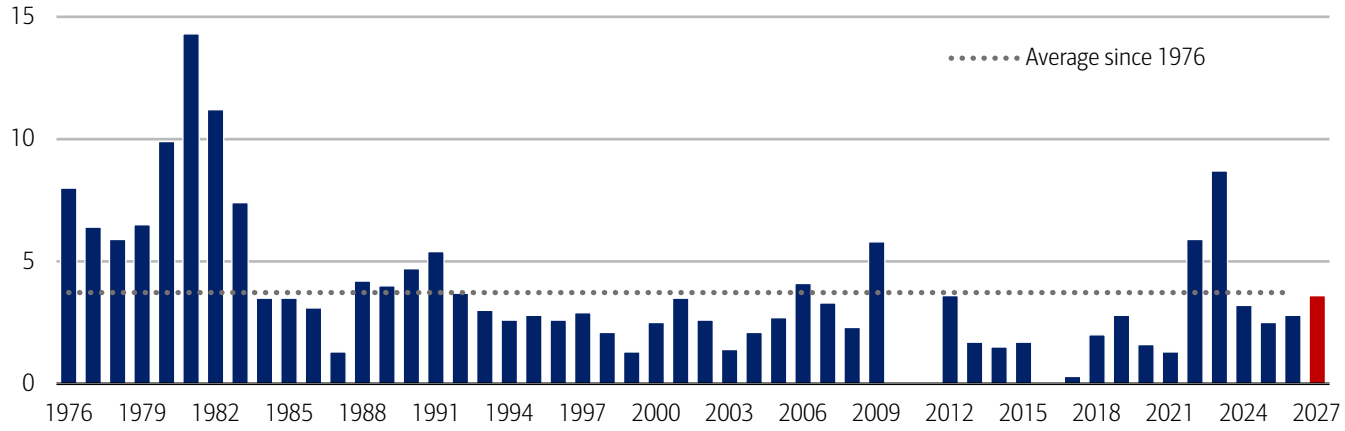

Still in our view there are some reasons for optimism around older generations spending outcomes.

For some older households in the middle of the income distribution, tax policy is likely providing some support to their spending growth. The One Big Beautiful Bill Act introduced a temporary deduction of up to $6,000 for each taxpayer aged 65 or older for 2025-2028, with the benefit phasing out above $75,000 of modified adjusted gross income for single filers and $150,000 for joint filers. This measure is likely lifting after-tax income and spending capacity for older households – particularly those in the middle of the income distribution.

However, households on lower incomes may see less benefit from these policies as they likely already owe limited federal income tax. For these households relying on Social Security either as their sole or as a large component of their income, the forthcoming annual cost-of-living adjustment (COLA) to social security benefits will likely be a more important determinant of their budgets for 2027. The announced COLA for 2027 is a rise of 3.6% (Exhibit 7) – the largest since 2023, though lower than the 8.7% rise in 2022.

Exhibit 7: The 2027 COLA increase is the largest since 2023 and close to the historical average

Social Security cost of living adjustments (% increase as of January effective date)

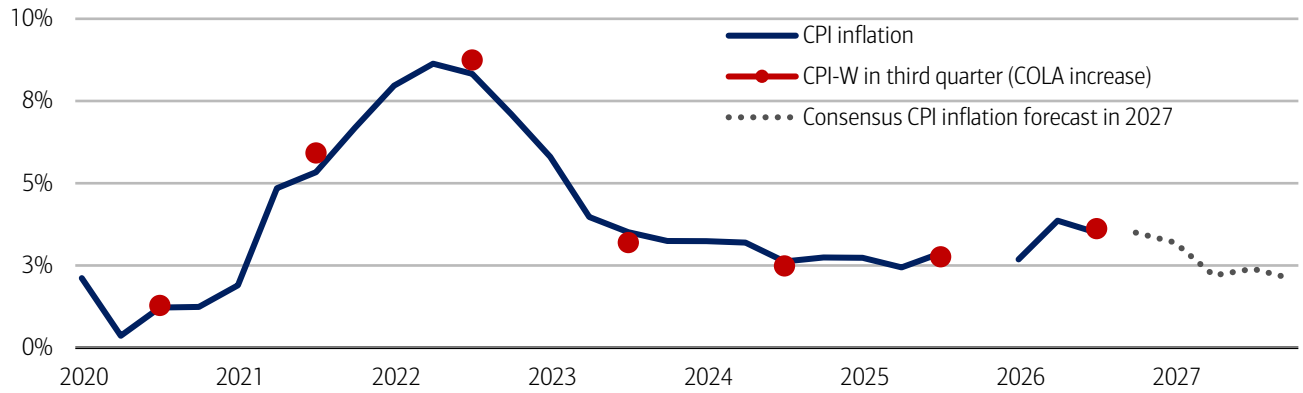

Source: US Social Security Administration (SSA)

BANK OF AMERICA INSTITUTE

The COLA increases are based on the year-over-year (YoY) % change between the third quarters of successive years in the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W) and are typically announced in October and effective the following January. If the COLA increase simply keeps benefits in line with inflation, why is it particularly interesting? For sure, many times it is not. But when inflation is close to a turning point, the increase can end up looking relatively high or low compared with inflation over the course of the following year. The 2022 COLA increase was a case in point, as inflation in the subsequent year slowed sharply. In our view, this was one reason older generations' spending growth was stronger than that of other age cohorts over 2022-2023.

Exhibit 8: Inflation is expected to decline next year

Consumer Price Index (CPI) (% YoY), third quarter CPI-W increases (red dots, % YoY) and latest consensus CPI forecast for 2027 (dotted line, % YoY)

Source: Haver Analytics, Bloomberg. Some fall 2025 months might be missing due to the government shutdown.

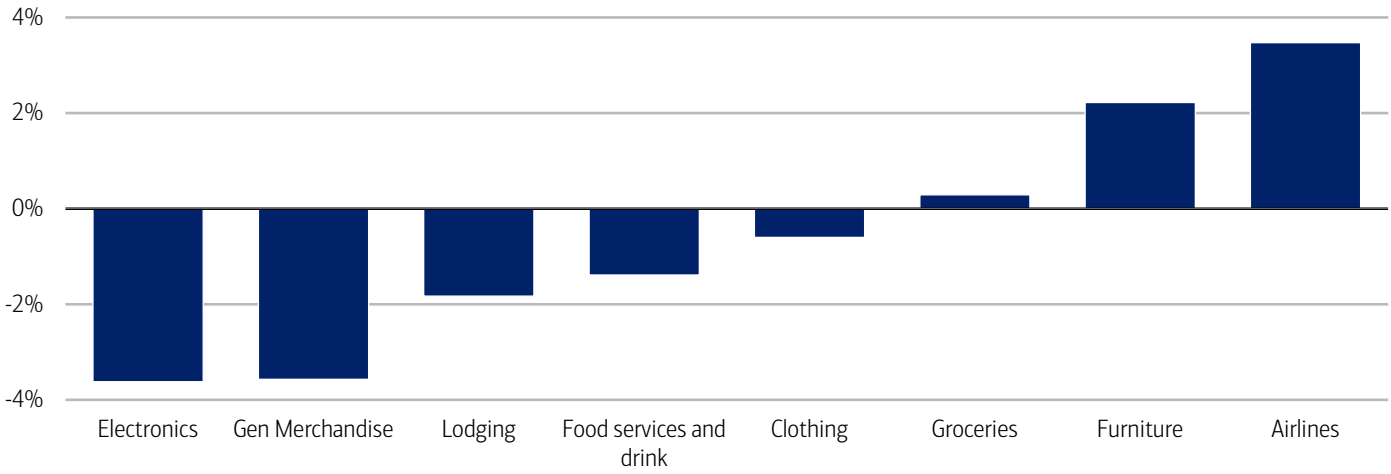

BANK OF AMERICA INSTITUTE

Regarding the 2027 COLA announcement, there are some parallels with 2022, albeit on a smaller scale. In particular, the consensus expectation is that CPI inflation is likely to cool over 2027, largely reflecting the lessening impact of higher gasoline prices (Exhibit 8).

So if these expectations prove correct, households that rely on Social Security may receive a more impactful boost to their budgets next year than they have for the last few, potentially narrowing the gap between older generations' spending and other households.

What categories of spending growth might benefit from this? It is hard to be sure, but notable growth deficits for older generations currently reside in discretionary areas like electronics, lodging and restaurants (Exhibit 9). Some of these may reflect the preferences of older households, but it could be that there is room for some narrowing in these areas.

Exhibit 9: Large spending growth gaps for older households exist in a range of discretionary goods and services
Difference between older generations' (baby boomer and traditionalist) spending and overall households' YoY spending growth by category (three-month moving average, percentage points)

BANK OF AMERICA INSTITUTE

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

The differences between the total and per household card spending growth rate (if discussed) can be explained by the following reasons:

1. Overall total card spending growth is partially boosted by the growth in the number of active cardholders in our sample. This could be due to an increasing customer base or inactive customers using their cards more frequently.
2. Per household card spending growth only looks at households that complete at least five transactions with Bank of America cards in the month. Per household spending growth isolates impacts from a changing sample size, which could be unrelated to underlying economic momentum, and potential spending volatility from less active users.
3. Overall total card spending includes small business card spending while per household card spending does not.
4. Differences due to using processing dates (total card spending) versus transaction date (per household card spending).
5. Other differences including household formations due to young adults moving in and out of their parent's houses during COVID.

Any household consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level. Whenever median household savings and checking balances are quoted, the data is based on a fixed cohort of households that had a consumer deposit account (checking and/or savings account) for all months from January 2019 through the most current month of data shown.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards are excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

Store category aggregation for "more discretionary", "partly discretionary", and "mostly necessity" is defined as follows:

More discretionary: furniture, electronics, building materials, hobbies, miscellaneous stores, nonstore retail, clothing.

Partly discretionary: auto, health and personal care, general merchandise.

Mostly necessity: Gasoline, food and beverage.

We consider a measure of services necessity spending that includes but is not limited to groceries, utilities, and gasoline. Discretionary services includes but is not limited to charitable donations, leisure travel, entertainment, and professional/consumer services. Discretionary retail includes but is not limited to general merchandise, miscellaneous, clothing, electronics and furniture. It excludes categories like groceries and gasoline. Holiday spending is defined as items in which spending in the November-December period is usually at least 20% of total annual spending on the category. Value and premium grocers are determined judgmentally on a proprietary analysis of merchants by equity analysts. The "more discretionary" retail category includes furniture, electronics, building materials, online marketplaces, clothing retailers and miscellaneous stores; while "partly discretionary" retail contains auto parts and services, health and personal care retailers, general merchandise and "mostly necessity" retail contains gas and groceries.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Any reference to card spending per household on gasoline includes all purchases at gasoline stations and might include purchases of non-gas items.

Bank of America Proprietary Market Landscape Insights Study is an online quantitative survey among Bank of America customers and noncustomers sampled and balanced to provide a representative view of the U.S. adult population. Insights are based on aggregated and anonymized responses to surveys. Significance testing is done at the 90 percent confidence interval.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

Kicking and screaming: Child care costs persist

20 October 2026

Key takeaways

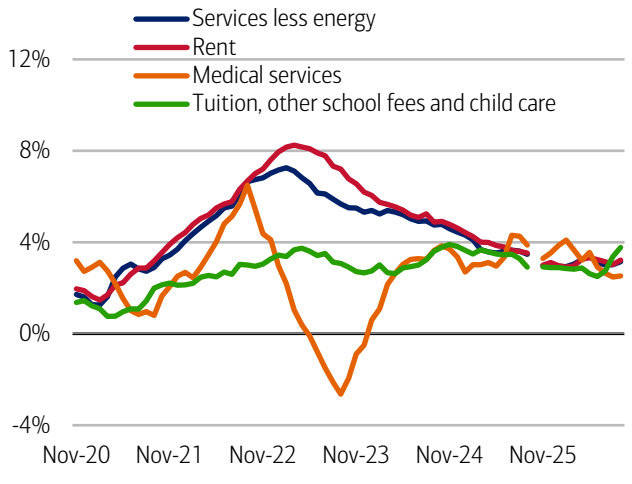

- Child care remains a growing financial burden for many households, even as growth in the median payment has moderated, according to Bank of America payments data. More families are paying more than $2,000 per month for care, suggesting affordability pressures are becoming increasingly concentrated among households facing the highest expenses.
- Child care cost pressures vary significantly across the country. Nashville and Jacksonville, FL posted the fastest year-over-year growth among major metro areas, while New York and Washington DC saw the biggest decrease in median payment growth, according to Bank of America payments data.
- Limited supply may continue to constrain access to child care for some households. Child care employment fell 0.7% year-over-year in September, suggesting provider capacity remains under pressure and could continue to affect household finances and labor force participation.

Child care costs outpace rent and medical services

Child care remains a significant expense for many families. In September, the growth in child care and other school-related fees surpassed other major household expenses such as rent and medical services, according to the Bureau of Labor Statistics (BLS) (Exhibit 1).

Yet, while child care prices continue to rise in official inflation data, median household payments have largely moderated since February, according to Bank of America data (Exhibit 2). More importantly, the growth in the number of households paying for child care has fallen since the start of 2025.

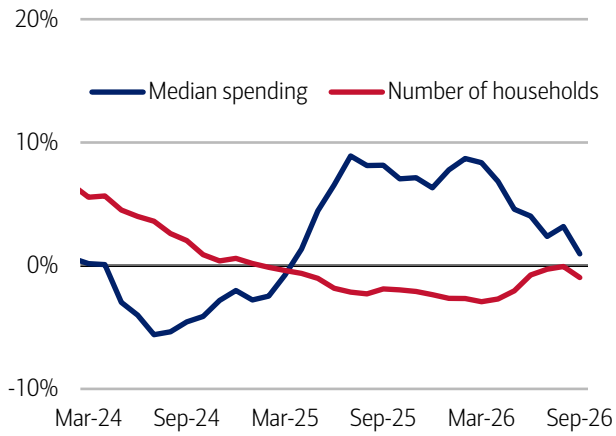

Exhibit 1: The cost of child care has surpassed other services such as rent in the consumer price index
Consumer price index by category (monthly, seasonally adjusted, YoY%)

Source: Haver Analytics

BANK OF AMERICA INSTITUTE

Exhibit 2: The median child care payment per household was up 1.0% year-over-year (YoY) in September but the number of households paying for child care fell 1.0% YoY
Median child care payment per household and number of households (monthly, three-month moving average, YoY%)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

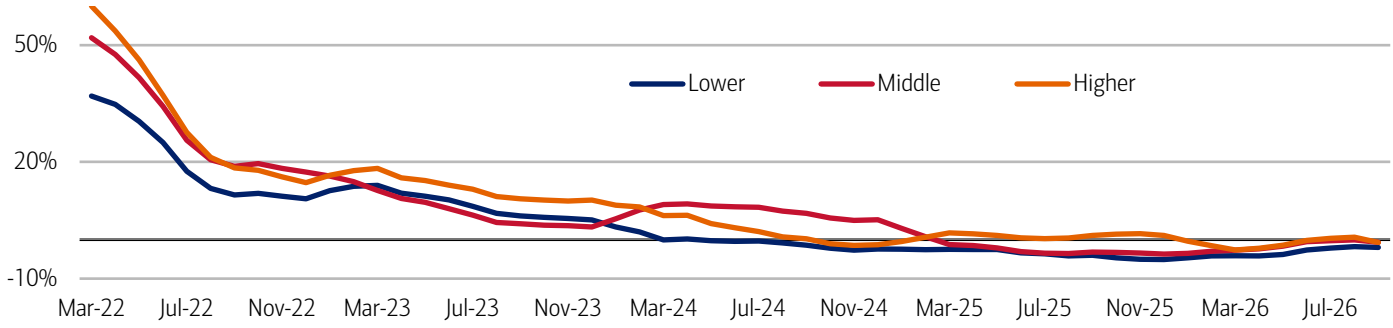

Fewer lower-income households are paying for child care

Why is Bank of America payment growth trending in the opposite direction of the Consumer Price Index? Households are likely changing the amount of care they use, which is reflected in slower growth in the number paying for child care. As more

households shift into lower-cost care (school-age, public pre-K, subsidized or free after-school programs), median payments can fall even as prices continue rising.

The decline in the number of households paying for child care may also reflect families seeking alternatives to formal care arrangements. Some may be relying more heavily on relatives, shifting parents' work schedules or dropping out of the workforce altogether to care for their children in response to elevated costs. This could explain why, among all income groups paying for care, the number of lower-income households has seen the biggest decline, falling 2.0% year-over-year (YoY) in September (Exhibit 3).

Exhibit 3: The number of lower-income households paying for child care has fallen the most, down 2.0% YoY in September
Number of households with child care payments (monthly, three-month moving average, YoY%)

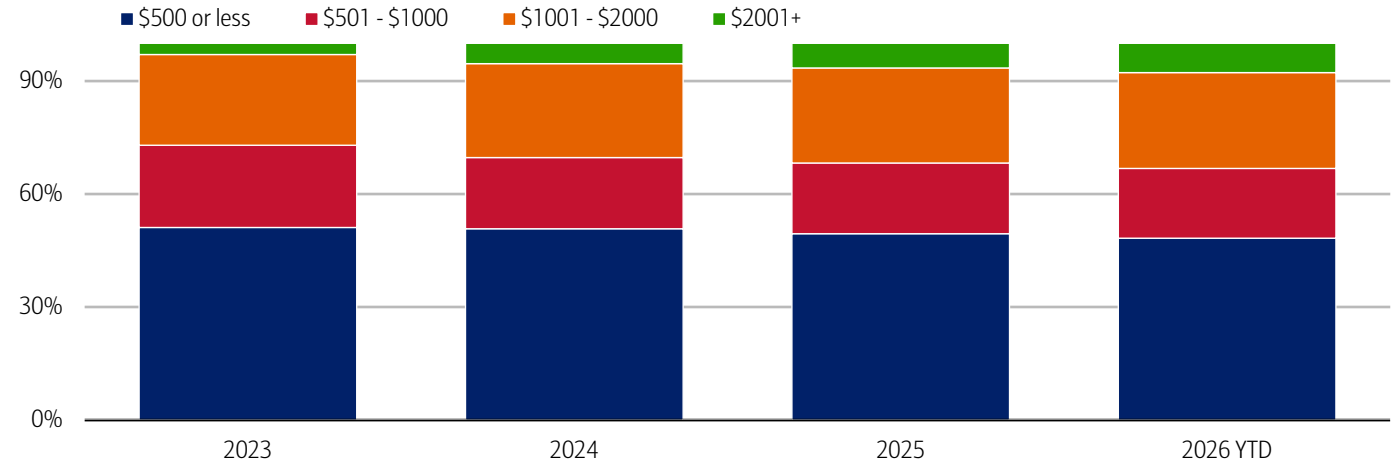

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

More families face larger monthly bills

Yet even as fewer households pay for child care, the share of those shelling out more than $2,000 per month has increased substantially (Exhibit 4). In fact, it has more than doubled since 2023, reaching 7.7% in 2026 year-to-date. Meanwhile, the share of those paying $1,000 or less has declined, suggesting higher monthly payments are becoming more common even as the national median grows more slowly.

Exhibit 4: The share of households paying >$2000 a month for child care has more than doubled since 2023
Monthly child care payments by amount (annual average, share of households, %)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

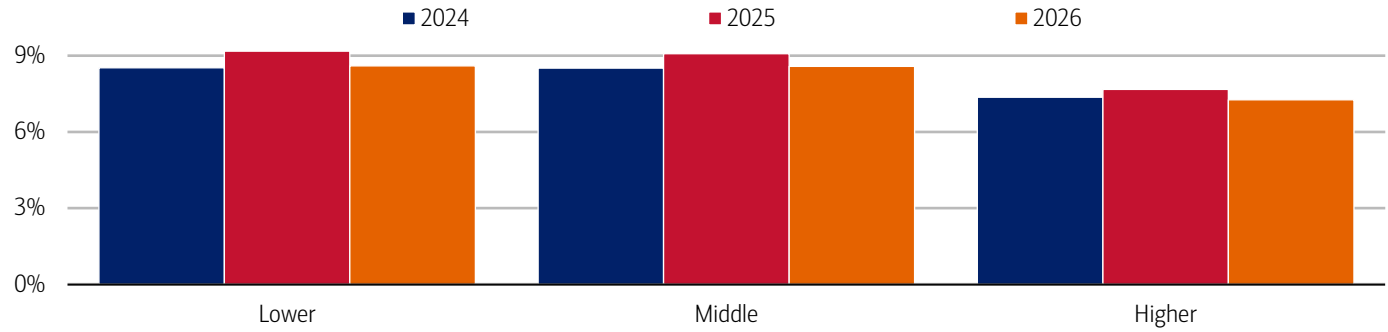

Rising costs take a bigger bite out of households' paychecks

What makes child care "affordable"? According to the U.S. Department of Health and Human Services, child care is considered affordable if it accounts for no more than 7% of family income. Yet, in Bank of America data, the average child care cost was 8% in September.

While an 8% share may not appear dramatically above the federal affordability benchmark of 7%, it represents an average across households' income levels. For families in high-cost metro areas or those paying more than $2,000 per month, the burden is likely considerably higher.

Notably, lower- and middle-income households see outsized shares of their pay dedicated to child care in Bank of America payments data, though this has moderated slightly from 2025 (Exhibit 5).

Exhibit 5: In September, the average child care payment was 8.6% of lower- and middle-income total households' pay, whereas for higher-income families it accounted for 7.3%
Average child care payment as a share of pay in September by income (annual, %)

Source: Bank of America internal data

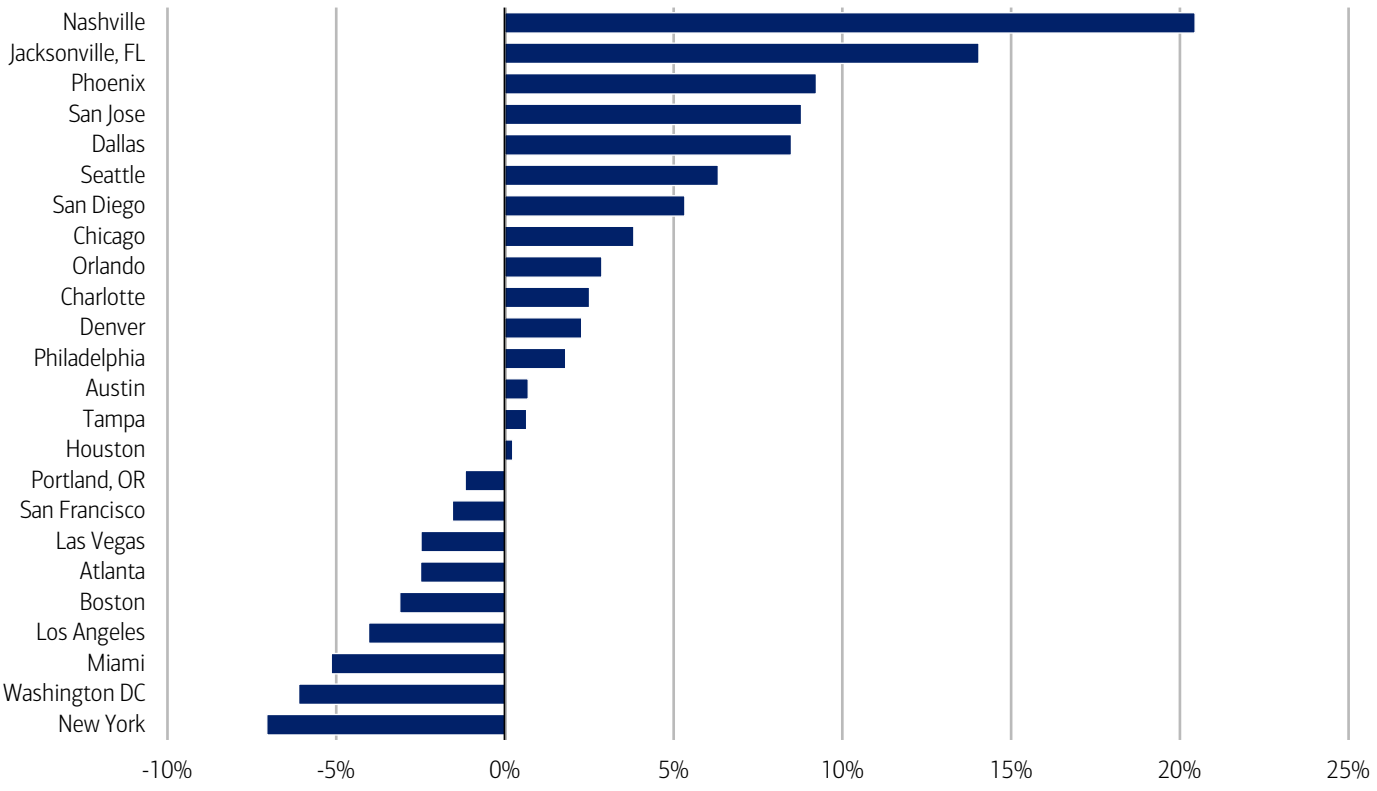

BANK OF AMERICA INSTITUTE

Where child care costs are climbing

Child care pressures also differ substantially by location. In Bank of America payments data, Nashville posted the fastest YoY median payment growth in September, followed by Jacksonville, FL and Phoenix (Exhibit 6). This dispersion of growth across the country suggests child care cost pressures are no longer confined to historically expensive coastal markets.

Interestingly, New York and Washington DC saw the sharpest decline in growth this year. Why might this be? The supply side of the market may help explain why – for example, New York City recently introduced universal Pre-K.[1]

Exhibit 6: Nashville and Jacksonville, FL saw the greatest increase in median child care payment growth among select cities in September

Fewer providers, higher costs

As of September 2026, employment in child care services was down 0.7% from a year earlier, suggesting the sector's workforce recovery has stalled. Fewer workers can constrain the number of available places or the hours providers offer. That may leave families facing longer searches, fewer workable arrangements or continued price pressure. In turn, access to care can influence parents' ability to enter, remain in or expand their participation in the workforce.

Exhibit 7: Employment within child care services fell 0.7% YoY in September
Employees by sector (monthly, seasonally adjusted, YoY%)

BANK OF AMERICA INSTITUTE

What are the economic implications of rising child care costs?

Child care costs may have important labor market implications for families with young children. Of those households paying for child care in 2026, more than half of them were Older Millennials (52%), followed by Younger Millennials (20%) and Gen X (16%), according to Bank of America payments data. This means child care costs weigh more heavily on Older Millennials.

The share of Older Millennial households receiving more than one paycheck has continued to grow from a year earlier, but the pace of that improvement has moderated over the past three months (Exhibit 8). Given that this group accounts for the majority of households paying for child care in Bank of America payments data, they may offer early signs of how affordability affects their employment decisions.

Exhibit 8: The share of Older Millennial households paying for child care that have more than one person with a paycheck has declined since 2021
Share of households with a child care payment with more than one person with a paycheck (%, monthly, three-month moving average)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

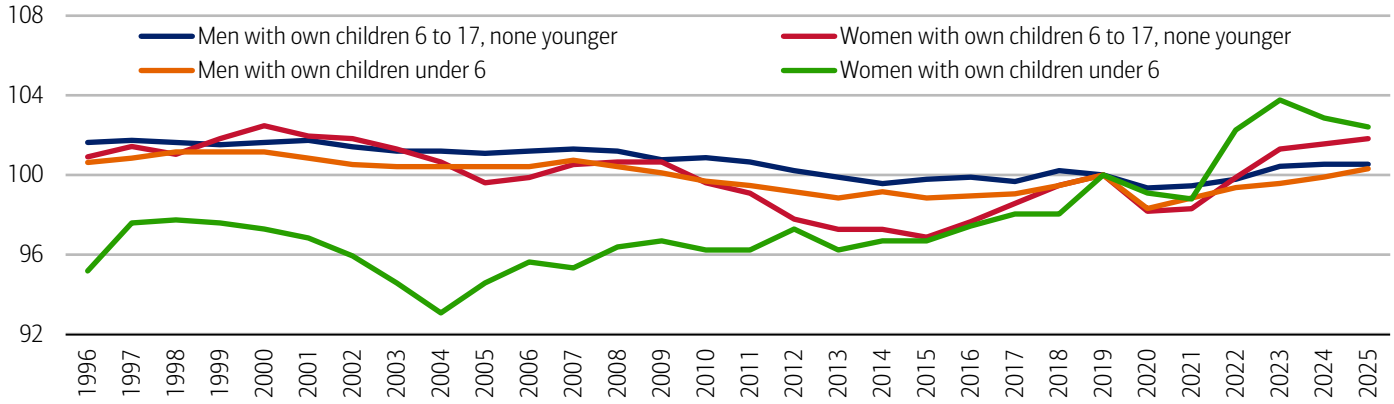

Child care challenges can weigh on women's employment

According to data from the American Time Use Survey, women continue to perform significantly more child care and household work than men, even as their participation in paid work has increased. This suggests that persistent gaps in access and affordability may have disproportionate consequences for women's employment. Indeed, the percentage of women who cited child care as a reason for temporary unemployment was nearly three times higher than men's in 2026, though the average fell from 2025, according to data from the BLS.

Yet labor force participation data indicates a more nuanced picture. Despite persistent child care pressures, mothers are participating in the workforce at rates that remain above their 2019 averages.

The strongest gains have occurred among women with children under age six, whose labor force participation rate remains well above pre-pandemic levels (Exhibit 9). Women with school-age children have also seen participation rise relative to 2019, though by a smaller margin.

Exhibit 9: In 2025, women with children under age six saw the greatest increase in their participation rate compared to the 2019 average
Annual estimates for labor force participation rates by sex and age of children (annual averages, indexed, 2019 average = 100)

Source: Bureau of Labor Statistics

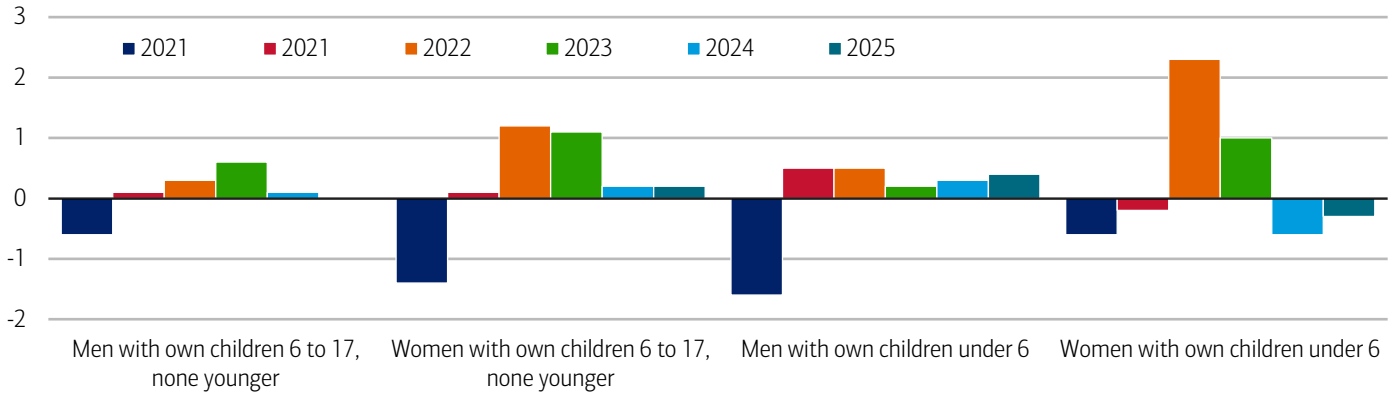

BANK OF AMERICA INSTITUTE

Mothers' workforce participation remains elevated, but recent gains have slowed

However, recent momentum has slowed. While mothers of young children experienced particularly large participation gains in 2022 and 2023, those have partially reversed in 2024 and 2025 (Exhibit 10).

In contrast, participation among women with children ages 6 to 17 has continued to edge higher. This signals that the post-pandemic increase in working has largely been sustained in this group, but the pace of improvement has moderated, especially for women caring for younger children.

Exhibit 10: The labor force participation rate for women with children under age six fell in 2025 from the prior year
Annual estimates for labor force participation rates by sex and age of children (annual averages, percentage point difference from prior year)

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Bank of America credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards is excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

If applicable, the consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level.

If applicable, any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Any reference to aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash and checks.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

Insurance costs hit the brakes

16 October 2026

Key takeaways

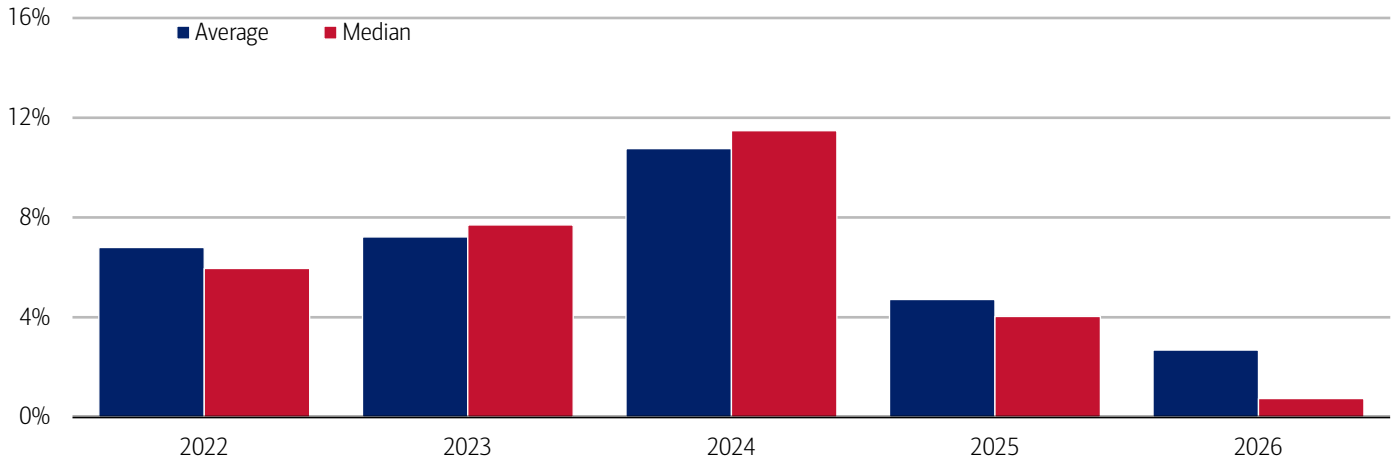

- Property insurance (e.g., auto, homeowners, renters) payment growth has slowed considerably, according to Bank of America payments data. Median payments rose just 1% year-over-year (YoY) in 2026, easing further from the 6% growth seen in 2025, after a roughly 12% increase in 2024, suggesting that many consumers are getting some relief from rising insurance payments.
- However, the moderation is uneven across consumers. Bank of America payments data suggests that Gen Z continues to experience insurance payment growth of nearly 6%, while increases for other generations are closer to 1% to 2%. Payments also rose nearly 1.5% for higher-income households but edged lower for those with lower incomes.
- Lower accident rates, easing vehicle prices, and softer major-purchase growth may be reducing cost pressures, but geography remains a major dividing line. Florida metros recorded declines of roughly 7% to 8%, while California and several Northeastern metros continued to see relatively strong increases.

Insurance payments stabilize after years of painful growth

The burden of higher property (e.g., auto, renters, homeowners) insurance payments may be easing for some. Notably, while the average payment increased 3% year-over-year (YoY), the median payment was only up 1%, according to Bank of America payments data. This suggests that most consumers have only seen a small increase in their premiums, though there may be a few outliers (Exhibit 1).

The latest data stands in contrast to just two years ago in 2024, when most consumers saw their insurance payments surge about 12% YoY, after a nearly 8% YoY increase in 2023.

Exhibit 1: Insurance payments have increased only modestly through August of this year, with growth peaking in 2024
Median and average insurance payments (September to August yearly, YoY%)

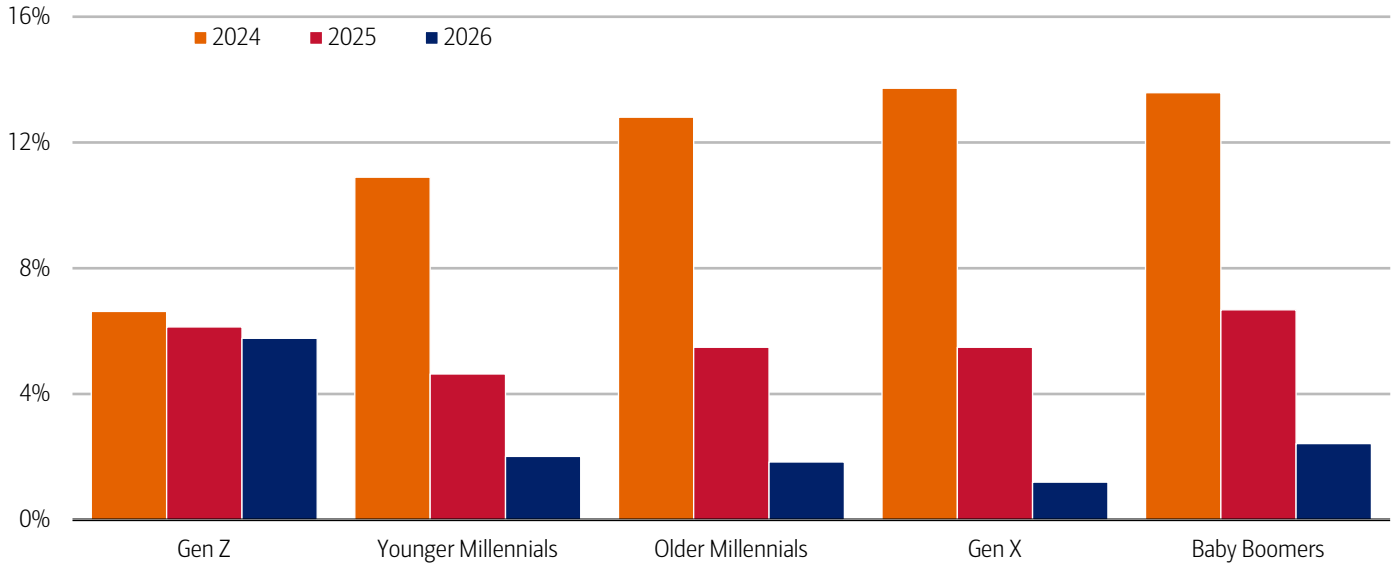

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Insurance payments by age show a similar pattern, with much stronger growth in 2024 across most generations followed by a cooling since then (Exhibit 2). Gen Z is the outlier here, with their payments still growing at a healthy rate, increasing almost 6% YoY for both 2026 and 2025, after a 7% increase in 2024. Meanwhile, Millennials and Baby Boomers experienced a 2% YoY increase so far this year, with Gen X only seeing around a 1% rise.

Exhibit 2: Insurance payment growth is easing significantly for every generation except Gen Z
Median insurance payments by age generation (September to August yearly, YoY%)

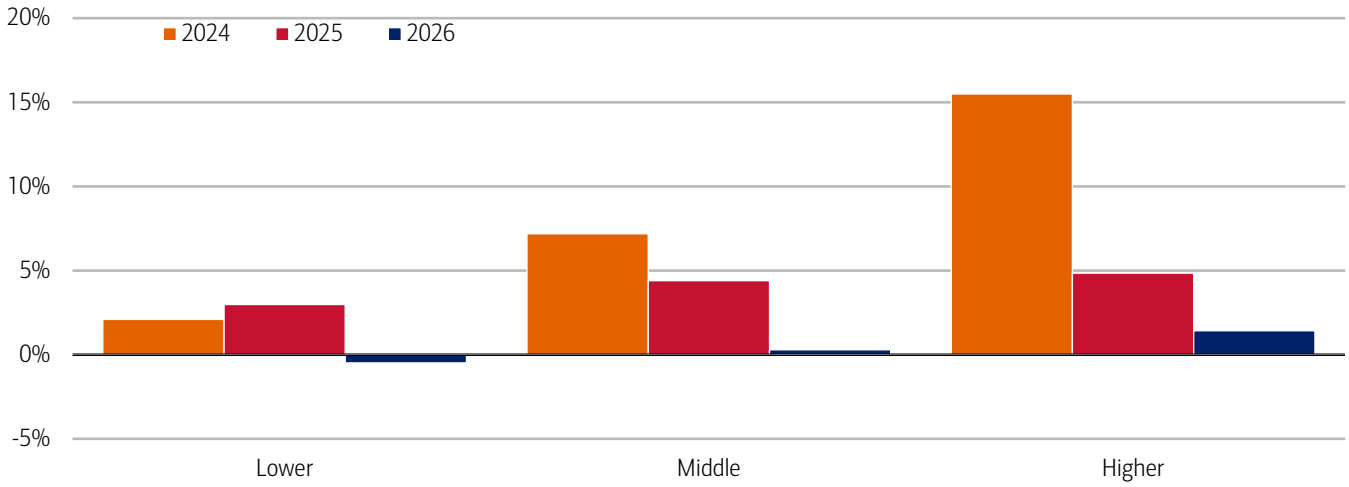

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Bank of America payments data by income provides even more insight. Higher-income households paid nearly 1.5% more in 2026 than they did a year ago, while middle-income households saw only modest increases or none at all (Exhibit 3). Conversely, lower-income households actually paid slightly less so far this year than they did last year.

Exhibit 3: Higher-income households are still paying more for insurance compared to last year, while lower earners are paying less
Median insurance payments by income cuts (September to August yearly, YoY%)

BANK OF AMERICA INSTITUTE

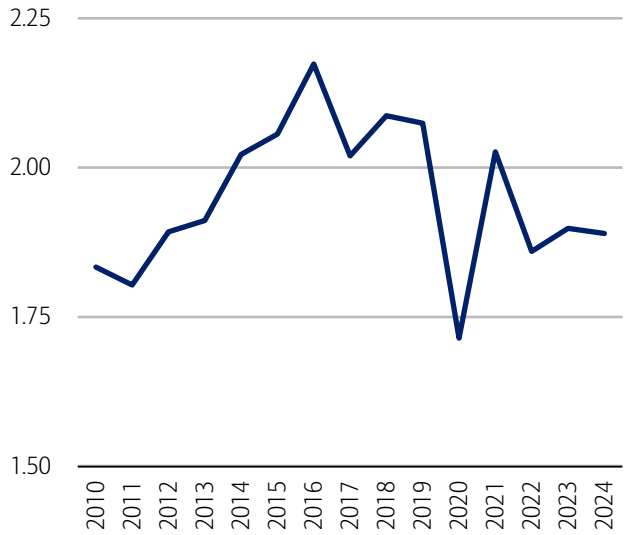

Fewer accidents and lower vehicles prices may be driving insurance payments down

But why might insurance payments be declining at all? One thing to keep in mind is that insurance companies often raise rates to cover events that occurred in previous years to recover costs, while adjusting for changing risks.

For example, the crash rate – the number of vehicle crashes per one million miles driven – suggests that there was a sharp rise in accidents in 2021, according to the Department of Transportation (Exhibit 4). Additionally, new and used vehicle prices increased significantly after the pandemic, according to Consumer Price Index (CPI) data from the Bureau of Labor Statistics (BLS) (Exhibit 5). So, insurers were not only facing more vehicle replacements due to a higher crash rate, but a higher cost to replace vehicles as well.

However, the crash rate mostly declined from 2021 to 2024, and the Department of Transportation reported that the number of accidents likely decreased again in 2025. Also, while the cost to maintain and repair vehicles has consistently grown since 2021, the price to replace vehicles peaked in 2022 and has eased since then – the latter likely a more important factor in insurance costs than the former. Additionally, while the CPI index for motor vehicle insurance has fallen 5% YoY, it's possible that this may partially be due to rebates, according to BofA Global Research. So, the price figured into CPI may not be fully realized by the consumer.

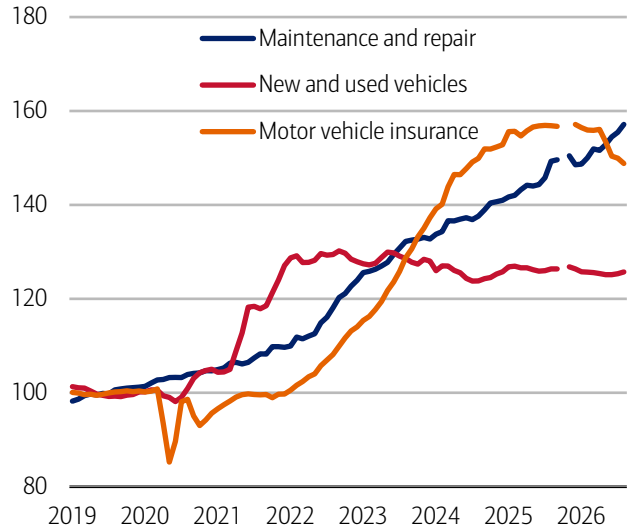

Exhibit 4: The rate of crashes is below pre- and post-pandemic levels

Exhibit 5: New and used vehicle inflation has eased since 2022
CPI for vehicle maintenance and repair, new and used vehicles and motor vehicle insurance (monthly, 2019 average = 100)

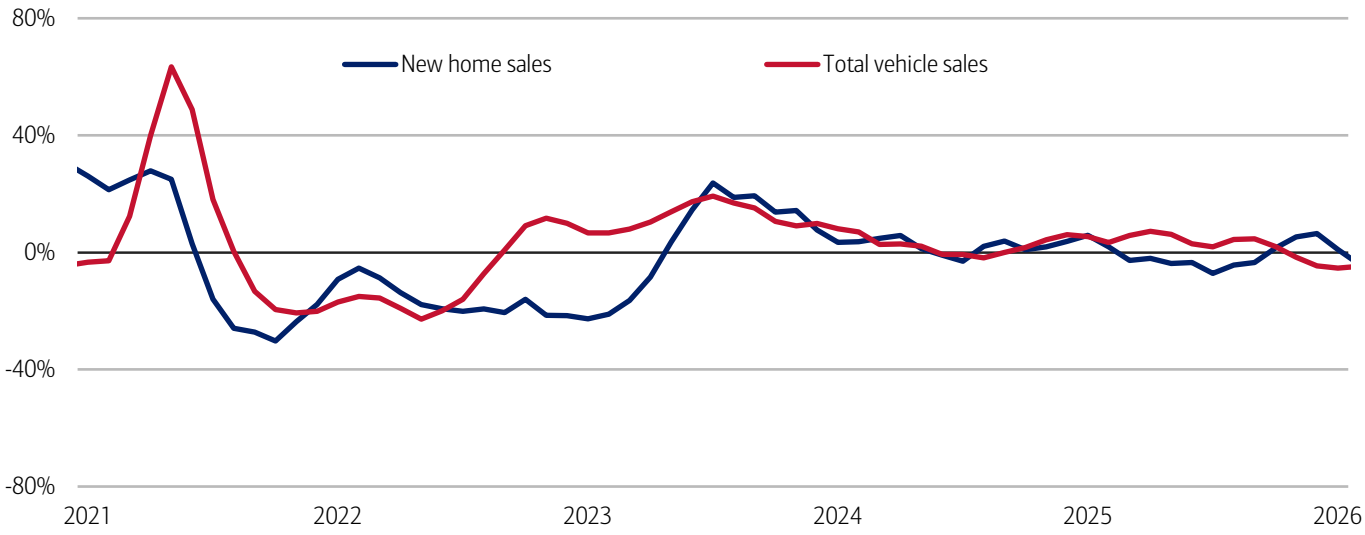

Source: BLS. Some fall 2025 months might be missing due to the government shutdown.

BANK OF AMERICA INSTITUTE

Another factor in the divergence between a declining CPI and rising insurance payments in our data may be the growth in the amount of property people are insuring now. Notably though, this growth has eased in recent years. YoY growth in both new home and total vehicle sales peaked in mid-2023 and has grown modestly, or even declined, since (Exhibit 6). And given that these major purchases are still K-shaped (read more in Autos: In gear, but the "K" is still in the headlights and On the move: Renovation over relocation?), it could help to explain the divergence in insurance payment growth across income cohorts.

Exhibit 6: Growth in new home and total vehicle sales peaked in mid-2023 due to a post-pandemic boom but has eased since

BANK OF AMERICA INSTITUTE

Florida's metros have seen the largest decline when compared to other major cities

Examining different cities across the US also sheds light on insurance trends. Consumers in major California metros saw the largest increases in 2026, following near double digit growth in 2025, likely driven by widespread property damage from wildfires, according to BofA Global Research (Exhibit 7). Major coastal metros in the Northeast like Boston and New York also experienced sizable increases as well.

Conversely, many cities throughout the Sun Belt like Houston, Nashville and Dallas saw flat or even declining insurance payments. BofA Global Research points to several reasons for these declines: part of the equation in this region is that the massive runup in the cost of property insurance and domestic migration to the region through 2024 has since eased or reversed course.

Exhibit 7: California major metros have seen steady insurance payment growth, while Miami metros have seen declines
Median insurance payments by core based statistical areas (September to August yearly, YoY%)

Source: Bank of America internal data

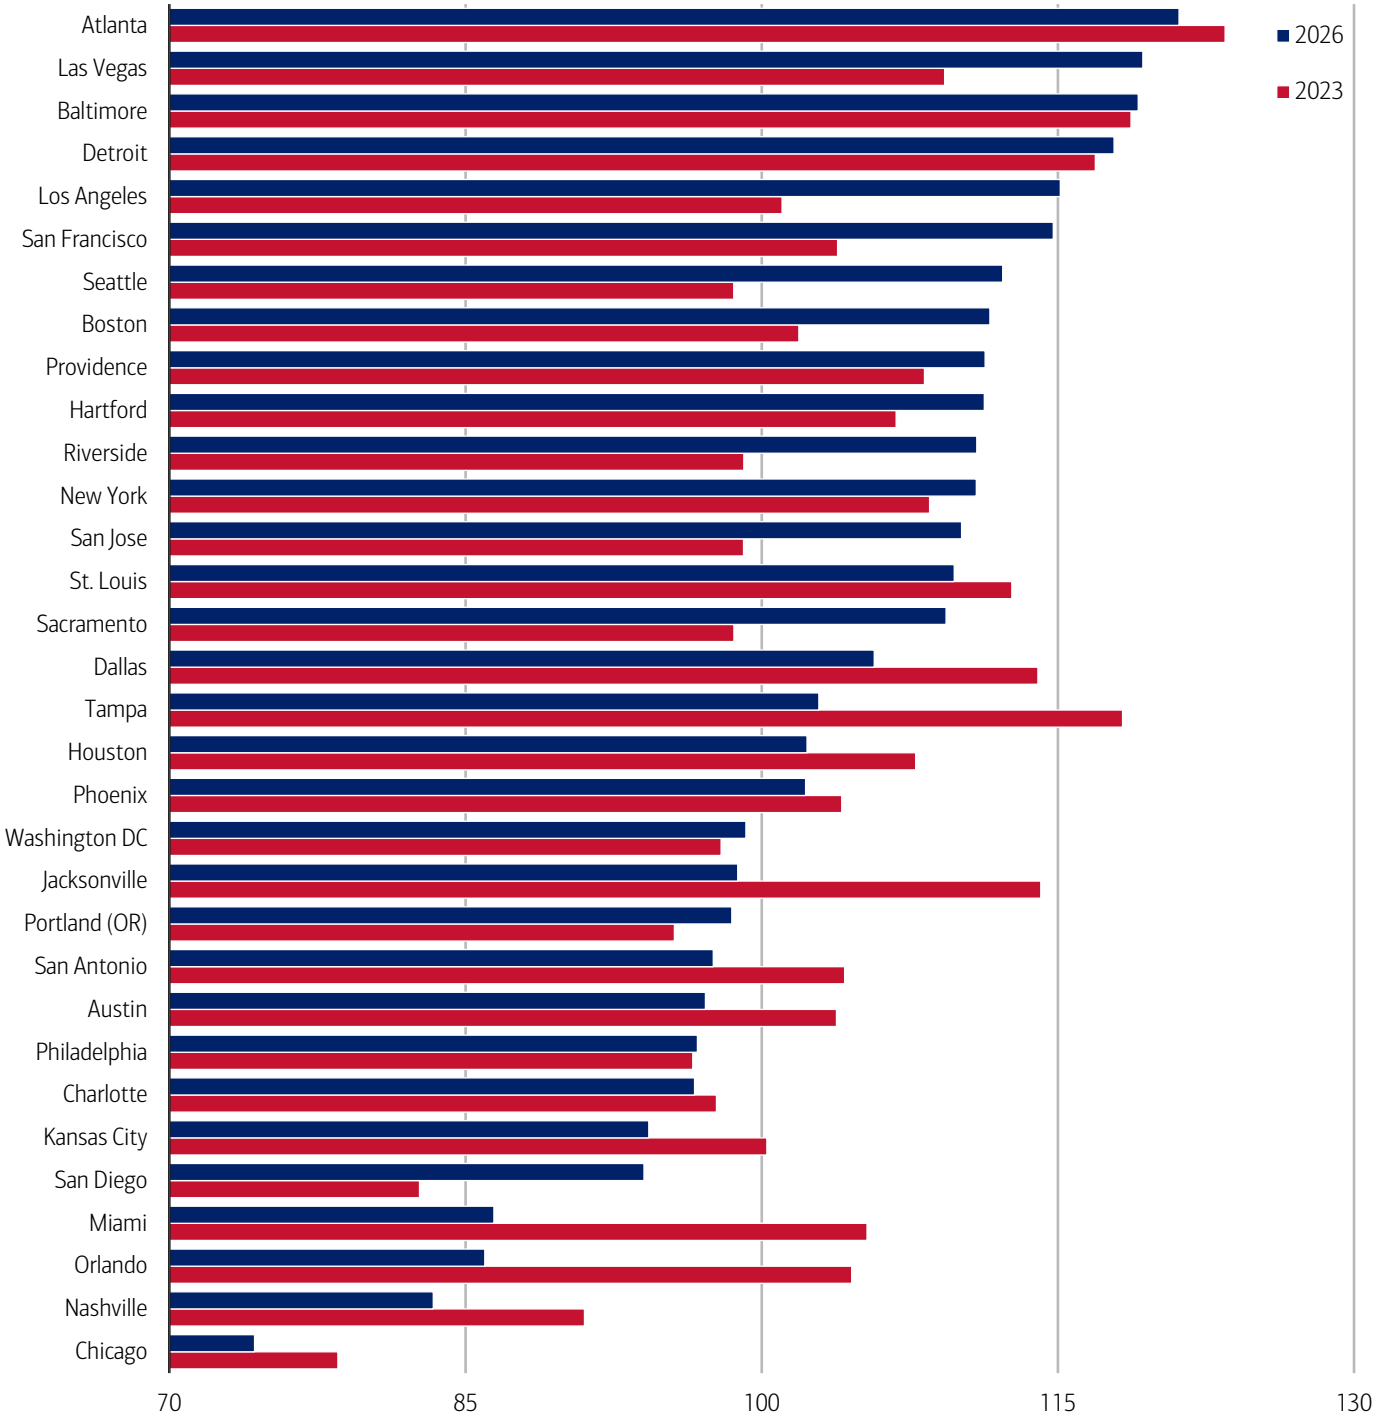

BANK OF AMERICA INSTITUTE

In Florida, legislation that went into effect in 2023, eventually made its way into insurance prices in 2025, leading to widespread declines in premiums. The state also has a "lookback period" of three years, where insurance profits can be deemed too high and a rebate is issued to consumers. It's possible this rebate is factoring into declines this year, as some carriers only allow rebates upon renewals.

The Sunshine State was a notable standout for declines, with Orlando, Tampa and Jacksonville each down around 8% YoY in 2026, followed closely by Miami with a 7% decrease. Additionally, Bank of America payments data suggests that Jacksonville, Miami and Orlando all had median insurance payments above the national level in 2023, though their payments were fell below that in 2026 (Exhibit 8).

Major metros in Texas also saw easing insurance payments relative to 2023, while Seattle, San Jose, and Riverside, CA are among the major metros that went from below the national median to above in the three-year period ending in 2026.

Exhibit 8: Chicago, Nashville, Orlando and Miami residents have some of the lowest insurance payments in the nation among major metros

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

The differences between the total and per household card spending growth rate (if discussed) can be explained by the following reasons:

1. Overall total card spending growth is partially boosted by the growth in the number of active cardholders in our sample. This could be due to an increasing customer base or inactive customers using their cards more frequently.
2. Per household card spending growth only looks at households that complete at least five transactions with Bank of America cards in the month. Per household spending growth isolates impacts from a changing sample size, which could be unrelated to underlying economic momentum, and potential spending volatility from less active users.
3. Overall total card spending includes small business card spending while per household card spending does not.
4. Differences due to using processing dates (total card spending) versus transaction date (per household card spending).
5. Other differences including household formations due to young adults moving in and out of their parent's houses during COVID.

Any household consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level. Whenever median household savings and checking balances are quoted, the data is based on a fixed cohort of households that had a consumer deposit account (checking and/or savings account) for all months from January 2019 through the most current month of data shown.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards are excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

Insurance payments include renters, auto or home, but do not include insurance escrowed into mortgage payments or deducted from a paycheck.

We consider a measure of services necessity spending that includes but is not limited to groceries, utilities, and gasoline. Discretionary services includes but is not limited to charitable donations, leisure travel, entertainment, and professional/consumer services. Discretionary retail includes but is not limited to general merchandise, miscellaneous, clothing, electronics and furniture. It excludes categories like groceries and gasoline. Holiday spending is defined as items in which spending in the November-December period is usually at least 20% of total annual spending on the category. Value and premium grocers are determined judgmentally on a proprietary analysis of merchants by equity analysts. The "more discretionary" retail category includes furniture, electronics, building materials, online marketplaces, clothing retailers and miscellaneous stores; while "partly discretionary" retail contains auto parts and services, health and personal care retailers, general merchandise and "mostly necessity" retail contains gas and groceries.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Any reference to card spending per household on gasoline includes all purchases at gasoline stations and might include purchases of non-gas items.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

Business Checkpoint: Looking into the logistics

15 October 2026

Key takeaways

- Small and mid-sized businesses entered Q3 in relatively solid financial condition, with profitability growth up across both groups, according to Bank of America business account data. Nearly half of estimated tariff payments had been refunded by September, though the share of these refunds relative to revenue has peaked.
- In Bank of America business payments data, logistics spending growth per client was up four times as much for small than mid-sized firms. Additionally, distribution and inventory transactions growth per client has outpaced spending since the spring of 2025.
- Growing transportation bottlenecks are re-emerging ahead of the holiday season. Trucking capacity has tightened as driver availability remains constrained, according to BofA Global Research. This has pushed freight rates higher and driven strong transportation sector payroll growth, particularly among mid-sized businesses, according to Bank of America payments data.

Business Checkpoint is a new, regular publication from Bank of America Institute. It provides a real-time view of the financial health, opportunities and challenges facing small and mid-sized businesses across the US economy, leveraging the depth and breadth of Bank of America's proprietary data. By analyzing activity among both small and mid-sized firms, Business Checkpoint offers timely insights into business profitability, hiring, investment and spending trends. Such data is not intended to be reflective or indicative of, and should not be relied upon as, the results of operations, financial condition or performance of Bank of America.

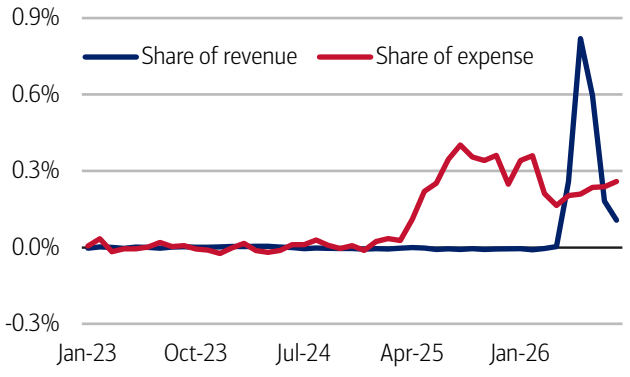

Businesses end Q3 in fair shape

While profitability growth remained positive for both small and mid-sized firms in the third quarter, small firms outpaced their mid-sized counterparts for the second consecutive quarter (Exhibit 2). Still, there's been a notable reversal in the profitability of mid-sized businesses, growing this quarter after declining slightly for the past two.

The continued rollout of tariff refunds is serving as a tailwind to some firms' cash positions. That is particularly true for small firms. According to Bank of America account data, by September approximately 47% of estimated International Emergency Economic Powers Act-related tariff payments had been refunded to companies with less than $50 million in annual revenue.

Exhibit 1: Tariff refunds as a share of income for businesses <$50M in annual revenue peaked in June

Share of tariff payments of income and expense (percentage point difference from 2023 average share)

BANK OF AMERICA INSTITUTE

Exhibit 2: Small firms' profitability growth outpaced mid-sized firms in Q3 2026

Profitability growth by firm size in 2026 (quarterly average, year-over-year (YoY)%)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

According to Bank of America business payments data, the percentage point difference in tariff refunds as a share of revenue for firms with less than $50 million in annual revenue spiked in June but dropped to nearly zero in September. At the same time, the percentage point difference in tariff payments as a share of expenses began rising again relative to the 2023 average (Exhibit 1). This suggests that while tariffs continue to affect companies, the refund program has provided temporary relief for some businesses.

Wholesale trade along with transportation and warehousing posted solid profitability growth across business size

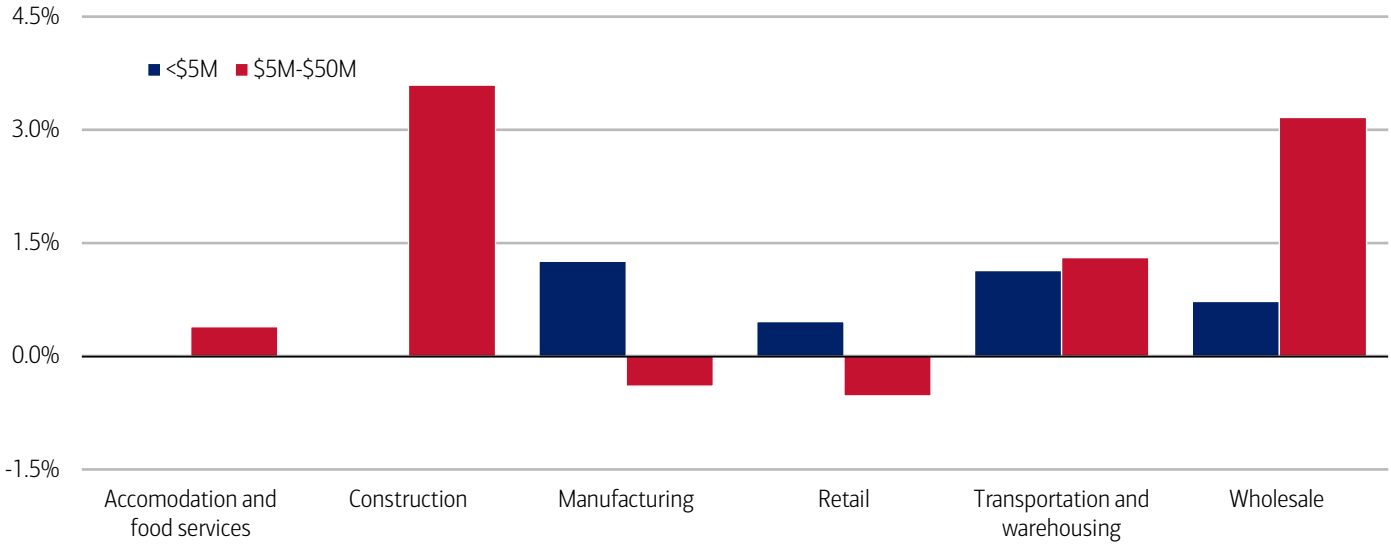

However, the benefits appear uneven. Such refunds have boosted cash flow, but they have not fully insulated firms from broader cost pressures.

Looking across industries, mid-sized construction and wholesale firms had the strongest profitability growth in September (Exhibit 3). Notably, transportation and warehousing, as well as wholesale trade were among the few sectors showing positive profitability growth for both small and mid-sized firms last month.

The persistence of logistics, freight and inventory-related cost pressures may help explain why profitability gains have remained relatively concentrated in transportation and wholesale trade. However, these sectors also have a higher exposure to rising gas prices within their margins (read more on this in the August Small Business Checkpoint).

Exhibit 3: For both small and mid-sized businesses, profitability growth was positive in transportation and warehousing as well as wholesale trade in September

Profitability growth by sector and business size in September (YoY%, six-month moving average)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

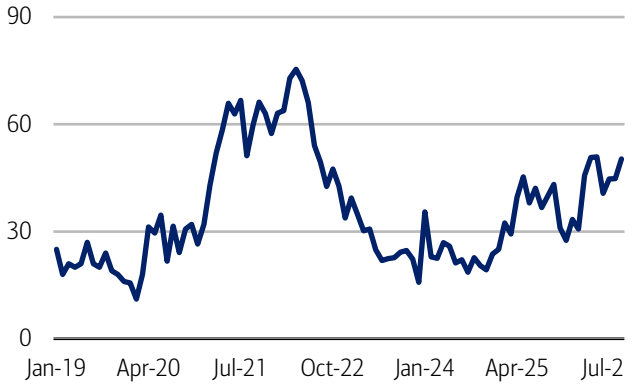

The cost of maintaining supply chains is rising

In fact, the prices paid component of the September services reading from the Institute for Supply Management indicates still-building price pressure for firms (Exhibit 4). This marked the highest reading since July 2022.

Using Bank of America internal data, we identified payments to logistics and freight companies to assess a key part of supply chain costs. In June, logistics and freight payments' growth per client from small businesses grew nearly 30%, though has moderated to 12.7% YoY in September (Exhibit 5). Meanwhile, mid-sized firms' payments growth in this category was up just 3.2% YoY in September.

The divergence suggests logistics costs may be disproportionately affecting smaller firms, who are typically less capable of absorbing rising costs than larger firms. Larger companies also often benefit from dedicated logistics contracts and greater purchasing power, while smaller ones may be more exposed to spot-market transportation costs and fluctuations in freight pricing.

BANK OF AMERICA INSTITUTE

Evidence of more moving parts in companies' supply chains

Yet there is increasing evidence that tariffs and geopolitics are adding complexity to small and mid-sized companies' supply chains.

In Bank of America payments data, average distribution and inventory transaction growth per business client has increased steadily since the spring of 2025 despite spending growth in this category falling in September (Exhibit 6). Rising transaction growth alongside softer spending growth suggests businesses may be engaging with more suppliers, shipments or inventory movements even as overall procurement outlays moderates.

Furthermore, in May 2026, the Global Supply Chain Pressure Index reached its highest reading since the summer of 2022 and has continued to remain elevated into October (Exhibit 7). This further emphasizes that transportation bottlenecks, delays and procurement challenges are becoming more common globally. While current readings remain below the extreme levels observed during the pandemic, the recent move higher indicates supply chain normalization may be reversing.

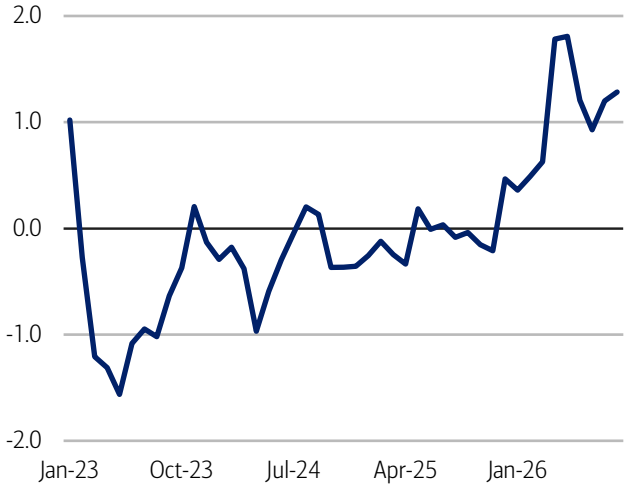

Exhibit 6: Average distribution and inventory transaction growth per business client has increased steadily since the spring of 2025

BANK OF AMERICA INSTITUTE

The trials of trucking

As of October 1, BofA Global Research's proprietary bi-weekly Truckload Demand Indicator (see Methodology) remained below its historical growth signal (Exhibit 9) and the Truck Capacity Indicator, which reflects shippers' views of available capacity, tightened significantly, falling from 39.2 to 28.4 (Exhibit 8). This suggests shippers are seeing fewer trucks available relative to demand than in the previous survey.

According to BofA Global Research, the current trucking upcycle is being driven by constrained supply rather than a significant improvement in freight demand. While any positive movement in demand is an important indicator as the industry moves into peak shipping season between late September and early December, tighter capacity appears to be the dominant force supporting freight rates.

Exhibit 8: Shippers' view of available capacity has fallen significantly as of October 1, 2026

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

Exhibit 9: The Demand Indicator has been sub-60 for the past two months after 4.5 months above
BofA Truckload Demand Indicator (bi-weekly)

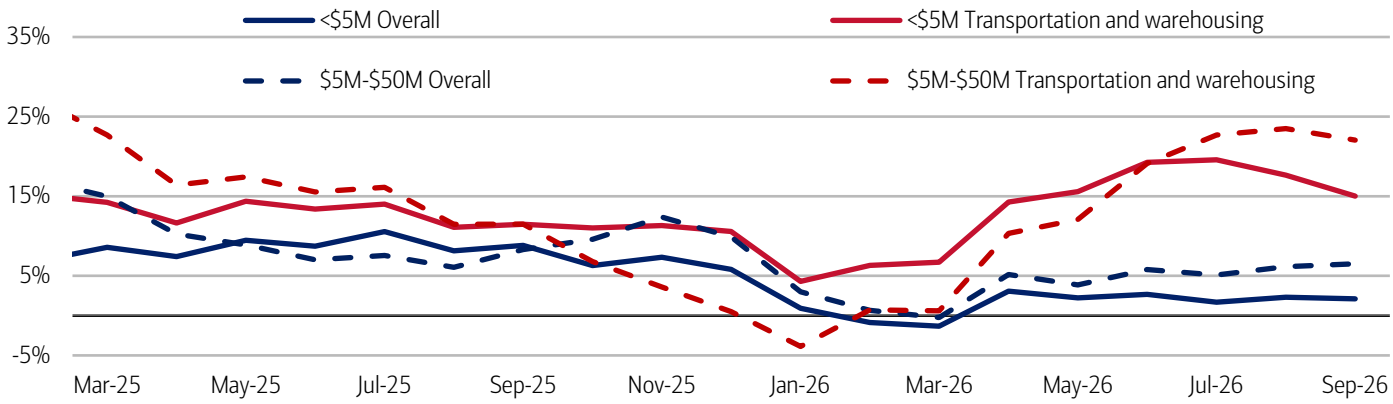

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

The reduction in capacity reflects several factors, including stricter commercial driver's license (CDL) and training requirements, increased compliance and enforcement measures, and other regulatory changes that have reduced the pool of qualified drivers. This has also likely driven some wage inflation within the industry. According to Bank of America payments data, transportation and warehousing payroll growth per client has surged since the start of the year, especially for mid-sized businesses (Exhibit 10).

Having to pay higher wages suggests labor shortages remain a challenge in the sector. Firms may increasingly need to offer higher compensation to attract and retain workers as trucking capacity tightens. In turn, such capacity puts upward pressure on freight rates, particularly in the spot market where small businesses may be more impacted.

Exhibit 10: Transportation and warehousing payroll growth has surged since the start of the year, especially for mid-sized businesses

BANK OF AMERICA INSTITUTE

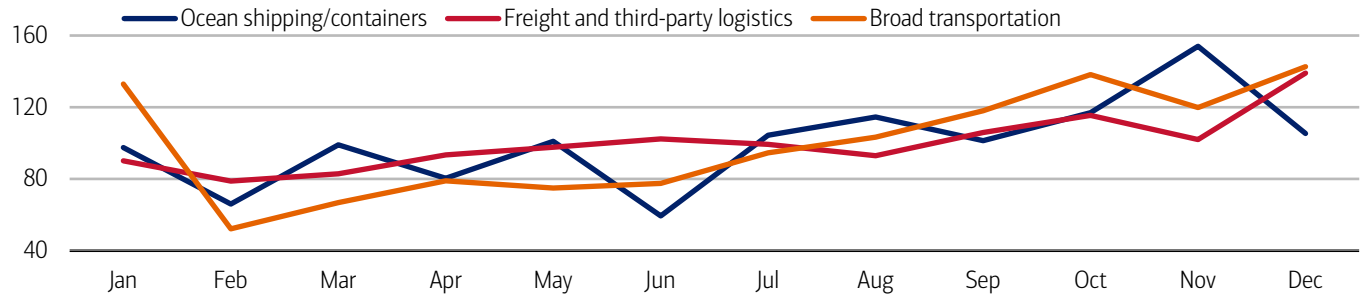

BANK OF AMERICA INSTITUTE

Logistics payments tend to increase in the second half of the year

September marks a key run-up to the holiday season (read more on signs of holiday spending in the October Consumer Checkpoint), with spending on ocean shipping, containers, and other transportation services steadily accelerating ahead of the peak shopping period.

In fact, over the past two years, the month of November has seen ocean shipping/container spending volumes well above their 2023-2025 monthly average (Exhibit 11). The seasonal pattern likely reflects inventory restocking and holiday-related shipping activity. Ocean shipping volumes typically accelerate during the fall months as businesses prepare for year-end demand.

Exhibit 11: Ocean shipping/container spending volumes were well above their 2023-2025 monthly average in November
Logistics and freight average payments by category (monthly, indexed, 100 = monthly 2023-2025 average)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

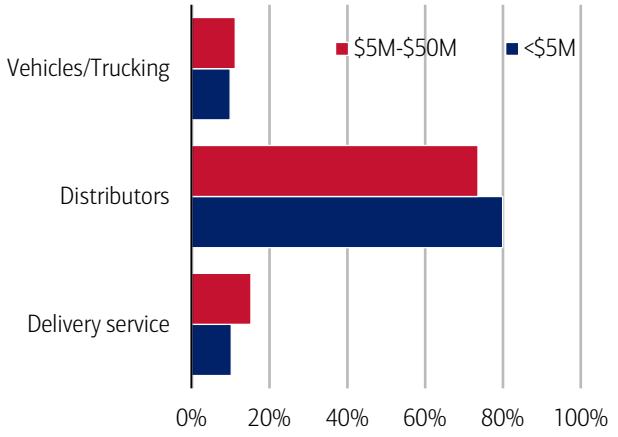

Distributors and inventory payments' growth fell ahead of holiday season

Changes in logistics and freight spending often provide an early signal of inventory trends, as distributors account for a large share of supply chain-related spending (Exhibit 12).

The sharp moderation in distribution and inventory spending growth per client for both small and mid-sized businesses indicates that much of the large-scale inventory accumulation seen earlier in 2025 has already occurred (Exhibit 13). In other words, businesses appear to be replenishing inventories for seasonal demand rather than significantly expanding stockpiles as they did earlier in the year.

Overall, businesses seem to be entering the holiday season in relatively stable financial condition, supported by tariff refunds and positive profitability growth. However, rising logistics costs, tighter trucking capacity and elevated supply chain pressures suggest operating conditions are becoming more challenging.

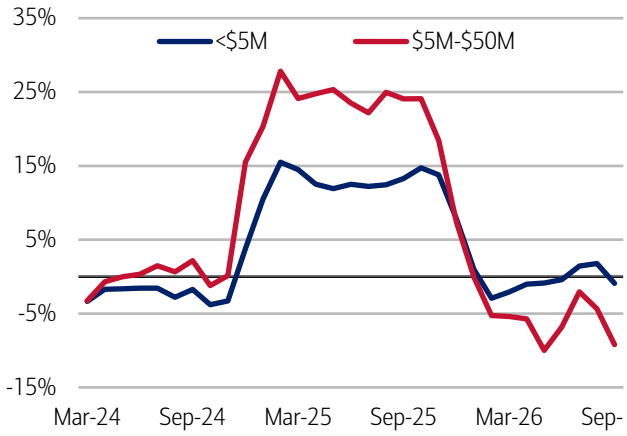

Exhibit 12: Distributors comprise a sizeable share of overall supply chain-related payments
Share of supply chain-related payments by category in 2026 by business size (%)

BANK OF AMERICA INSTITUTE

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any **Business** payments data represents aggregate spend from Small Business and/or Business Banking clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Business client data represents activity spending from active Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and are generally defined as under $5mm in annual sales revenue. Mid-sized businesses in this report include business clients within Bank of America and are generally defined as $5mm-$50mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

Revenue tiers are determined by the combination of following factors: 1) stated revenue on small businesses credit applications, 2) actual account inflow into Bank of America Deposit Accounts, and 3) third party revenue estimation.

The alternative hiring indicator consists of payments from Bank of America business clients to business-focused hiring firms which include both direct deposits through Automated Clearing House (ACH) and payments via credit and debit cards.

Supply chain-related spending is comprised of payments to logistics, freight, distribution, inventory, delivery service, and trucking companies. These are identified from merchant names and MCC codes.

BofA Global Research's trucking indicators are a bi-weekly diffusion-style survey of shipper demand expectations over the next 0–3 months, built from responses from surveyed shippers.

Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

Consumer Checkpoint: Strength in numbers

09 October 2026

Key takeaways

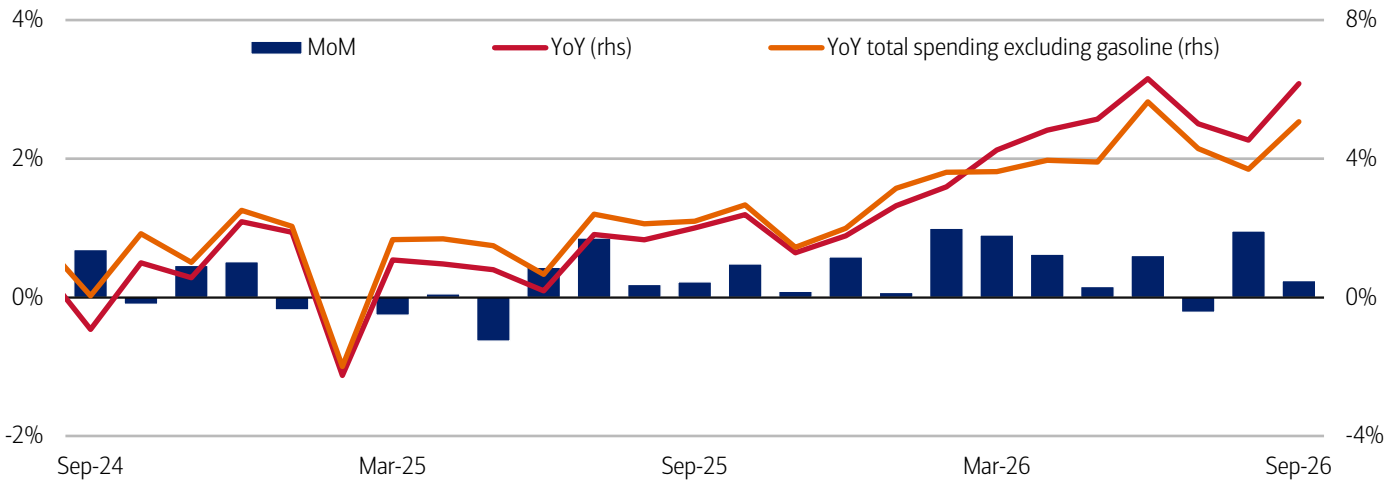

- Consumer spending remained very solid in September. Bank of America aggregated credit and debit card spending per household rose 6.2% year-over-year (YoY), or 5.1% excluding gasoline, both the third strongest growth rates over the past four years. Month-over-month (MoM) spending was more muted, especially without gas.
- Spending shows considerable breadth: the vast majority of discretionary retail and services categories are showing growth. Moreover, this strength extends across income cohorts, with the ongoing recovery of lower- and middle-income households' spending growth.
- With the winter months fast approaching, holiday spending is already increasing at a solid rate, though it's still early. In Bank of America deposit data through September, buy now, pay later (BNPL) usage is rising but not at a rate that is overly concerning. However, nearly one in every five households that use BNPL has a repayment of over $500.

Consumer Checkpoint is a regular publication from Bank of America Institute. It aims to provide a holistic and real-time estimate of US consumers' spending and their financial well-being, leveraging the depth and breadth of Bank of America proprietary data. Such data is not intended to be reflective or indicative of, and should not be relied upon as, the results of operations, financial conditions or performance of Bank of America.

A solid September for spending

Consumer spending continued to look solid in September. Bank of America total aggregated credit and debit card spending per household rose 6.2% year-over-year (YoY), while spending excluding gasoline increased 5.1% YoY. Notably, both are the third strongest growth rates in the past four years. Seasonally-adjusted total card spending rose 0.2% month-over-month (MoM), while spending excluding gasoline was little changed. Overall, spending growth remains well above the 2025 average rate (Exhibit 1).

Exhibit 1: Total card spending per household rose 6.2% YoY and 5.1% YoY excluding gasoline in September
Total card spending growth per household, based on Bank of America aggregated credit and debit card data (monthly, MoM%, seasonally adjusted (SA)) and (monthly, YoY%, non-SA, right-hand side (rhs))

BANK OF AMERICA INSTITUTE

Most spending categories are growing

One striking thing about recent card spending, in our view, is that it is well balanced across categories. For example, both spending on retail (excluding gasoline) and services grew strongly YoY in September, at 3.5% and 5.4%, respectively. Meanwhile, retail spending is showing notably better momentum than in 2025 (Exhibit 2).

Exhibit 2: Spending is rising across retail and services
Retail (excluding gasoline) and services card spending per household (monthly, seasonally adjusted, index January 2025 = 100)

Source: Bank of America internal data

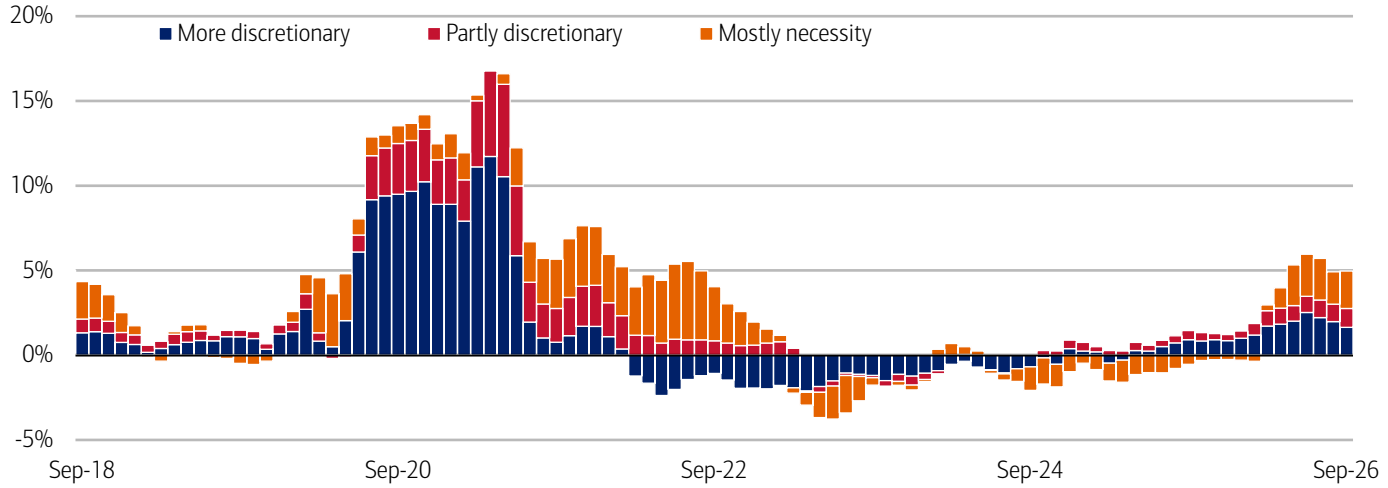

BANK OF AMERICA INSTITUTE

Well balanced across "nice-to-have" and "need-to-have" retail categories

Is the momentum in retail spending reflective of "nice-to-have" discretionary or "need-to-have" necessity spending? In retail, this is a nuanced question, as many categories sit in a gray area between "necessity" and "discretionary". General merchandise stores, for example, sell both essentials like groceries as well as nice-to-have electronics or even jewelry.

In Exhibit 3, we account for this by grouping retail spending into "more discretionary" (furniture, electronics, building materials, online retailers, clothing retailers and miscellaneous stores), "partly discretionary" (auto, health and personal care retailers, general merchandise) and "mostly necessity" (gas and groceries). Even within these categories the edges will be blurred, but the overall impression is that retail spending growth is widely distributed, with spending rising across all fronts. One caveat: "mostly discretionary" spending has been making a smaller contribution since June.

Exhibit 3: Retail spending is distributed across discretionary and necessity categories
Percentage points contribution to YoY growth by type of retail spending (three-month moving average)

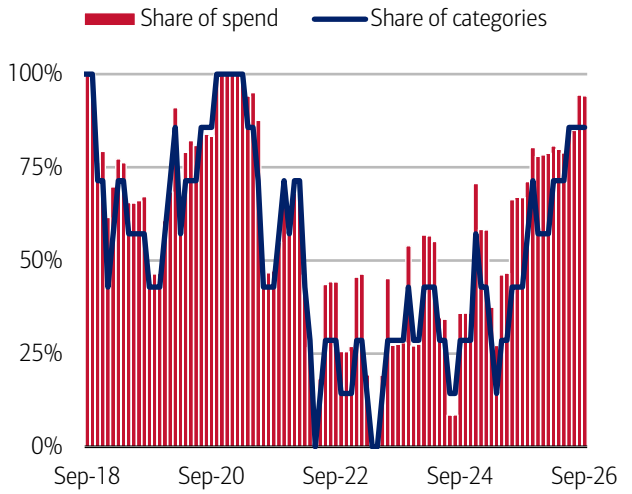

Source: Bank of America internal data. See methodology for category aggregation definitions.

BANK OF AMERICA INSTITUTE

Looking at the share of "more discretionary" retail spending categories that are increasing YoY underscores that growth is well balanced and broad-based (Exhibit 4). Non-store and online retailers and miscellaneous stores saw some of the fastest growth, while furniture and building materials were among the laggards, though other durable categories showed some strength.

While some of this spending growth likely reflects the impact of higher prices pushing up spending across a swathe of categories, looking just at transactions as a proxy for volumes shows a similar picture, with only slightly less diffusion (Exhibit 5).

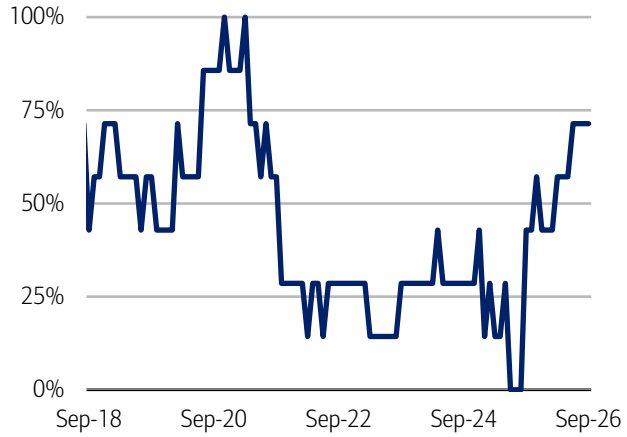

Exhibit 4: Nearly 86% of categories are experiencing positive spending growth, accounting for over 94% of retail spending

BANK OF AMERICA INSTITUTE

For services, growth is driven mostly by discretionary spending

In services spending, on the other hand, the boundaries between discretionary and necessity spending are often clearer. Travel spending (e.g., airlines, lodging) can be thought of as, by and large, discretionary. At the same time, utility bills, rent and insurance payments are necessities.

And in services, discretionary spending remains the clear driver, accounting for over three-quarters of YoY spending growth in September (Exhibit 6). Leisure and housing services are major components of growth, though travel and restaurants also made positive contributions. However, as we noted last month strength in airline spending largely reflects price rises rather than transactions growth (read more in Consumer Checkpoint: Still sizzling).

Exhibit 6: Services spending growth has been mostly driven by discretionary spending over the past year
Percentage points contribution to growth by type of services spending (three-month moving average)

Source: Bank of America internal data

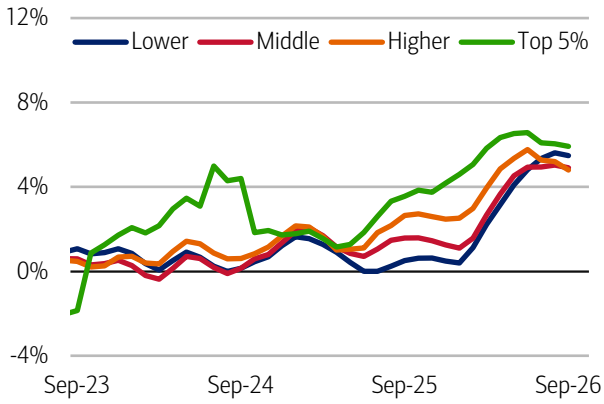

BANK OF AMERICA INSTITUTE

Lower-income households' spending outpaced all but the top 5%

The breadth in spending growth across categories is also evident across income cohorts. In September, lower-income households' total card spending growth was 5.5% YoY, while the equivalent figures for middle- and higher-income households were 4.9% and 4.8% YoY, respectively. The top 5% of households by income continue to show the fastest spending growth, 5.9% in September, though this has eased somewhat (Exhibit 7).

Overall, the divergences across income cohorts are much smaller than they were in 2025 and the first three months of this year. Just focusing on spending excluding key necessities (gasoline, food and utilities) doesn't meaningfully change the picture of convergence across income cohorts (Exhibit 8).

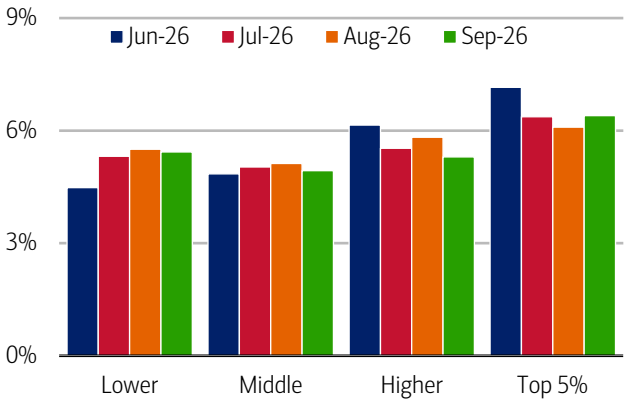

Exhibit 7: The top 5% saw the strongest spending growth of any income cohort…

Discretionary card spending per household by income tercile and the top 5% (three-month moving average, YoY%, SA)

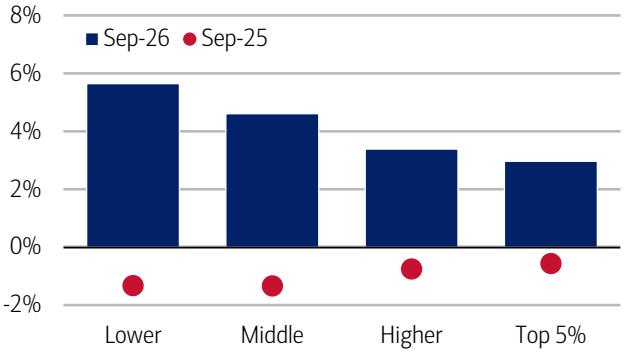

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

The strength in lower- and middle-income households' discretionary spending is occurring despite necessity spending shifting from a tailwind to a headwind over the past year amid rising gas prices (Exhibit 9). In our view, a key component of why these households have been able to combine rising necessity spending with strength in discretionary is the labor market and a recovery in their after-tax wage growth (Exhibit 10).

In September, lower-income wage growth eased to 4.5% YoY from 4.7% YoY in August, while growth for middle- and higher-income households rose to 3.8% and 3.7% YoY, respectively. These changes were modest, and lower-income households are continuing to see faster after-tax wage growth than other cohorts, a notable turnaround from the "K-shaped" pattern we observed over much of 2025 and 2026.

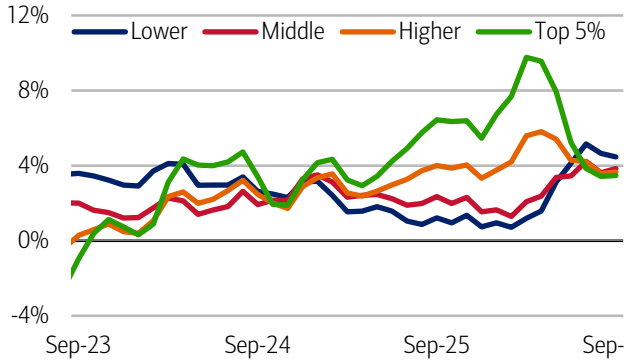

Exhibit 9: Necessity spending has gone from a tailwind to a headwind across all income cohorts

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Should we be concerned about the easing in household spending and after-tax wage growth for those with the top 5% of incomes? For now, probably not, as in our view this spending growth is likely being driven by wealth effects rather than wage gains. Absent a sharp correction in equity markets, there is little reason to expect them to retrench their spending. However, developments here are worth watching as this cohort comprises a significant proportion of overall consumer spending. They also tend to make outsized contributions to several discretionary spending categories (Exhibit 11).

Exhibit 11: The top 5% of households by income make up a disproportionate amount of spending in highly discretionary categories

BANK OF AMERICA INSTITUTE

With summer gone, thoughts turn to the holidays and BNPL...

Now that summer is over, the next big gauge of consumer momentum is how people spend during the run-up to, and over, the holiday season. It is early days, but September spending on holiday items ran well ahead of 2025 (Exhibit 12). Given the backdrop of firmer after-tax wage growth and breadth across retail and services categories, this is perhaps not surprising. However, some of this spending strength could be due to rising prices as opposed to more purchases.

Exhibit 12: It's early days, but holiday spending is strong so far this year
Card spending per household for holiday items by year (seven-day moving average, index September 2025 average = 1)

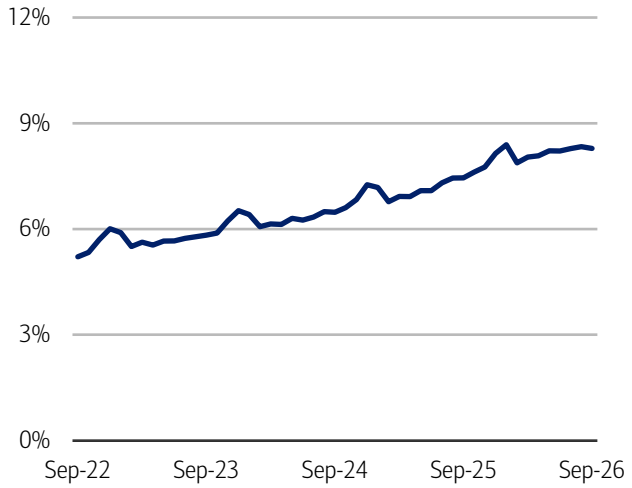

Source: Bank of America internal data
Note: Holiday items include all merchant category codes for which spending in November through December is at least 20% of total annual spending in the category.

BANK OF AMERICA INSTITUTE

A concern often raised as we move into the holidays is whether consumers will lean on less traditional forms of credit such as buy now, pay later (BNPL) to finance their spending. Frequent BNPL users tend to have higher credit card utilization rates (read more in: Do consumers have wiggle room to absorb higher gas prices?).

Looking at the share of households in Bank of America deposit data with a BNPL payment, we do tend to see a seasonal rise over the holidays (Exhibit 13), though in past years, these increases have quickly reversed. Further, while the underlying trend in BNPL usage is upwards, there are no signs of a sharp acceleration. We do, however, see some evidence that BNPL is being used to finance more expensive purchases, with the share of households making repayments above $500 rising, albeit relatively slowly (Exhibit 14).

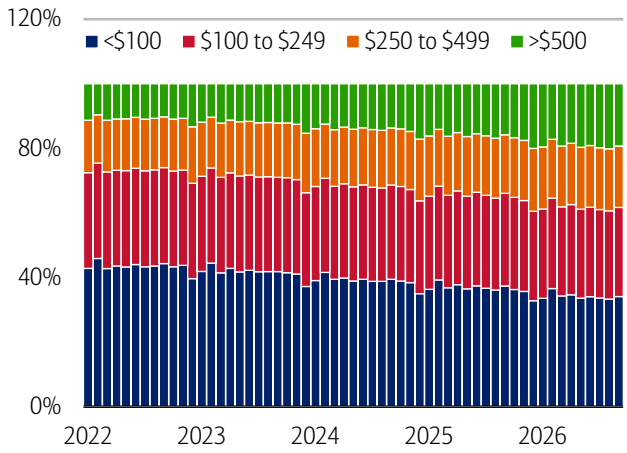

Exhibit 13: 8.3% of Bank of America households had a BNPL payment in September
Share of households with a BNPL payment in the month (monthly, %)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Exhibit 14: Almost one in five households with BNPL usage has a repayment of over $500
Share of households with BNPL payments by repayment amount (monthly, $ amounts)

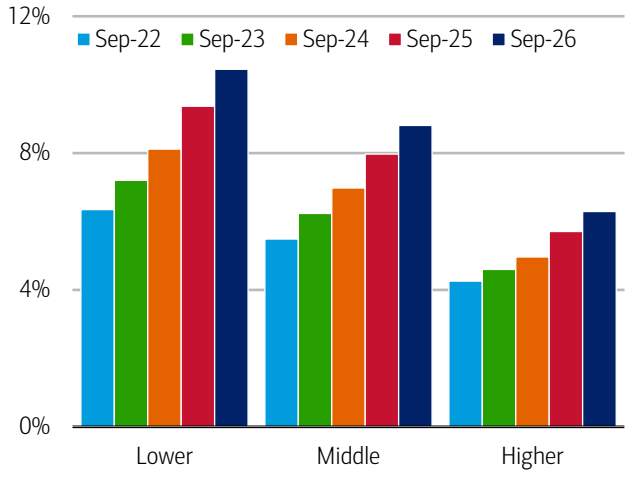

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

The tendency towards greater usage is occurring across income cohorts, though is somewhat more pronounced for lower-income households (Exhibit 15). However, higher-income households have the largest share of BNPL payments above $500 (Exhibit 16). Overall, in our view, the increase in the share of BNPL users heading into the season does not appear too concerning, though the rate of usage for some BNPL consumers does bear watching.

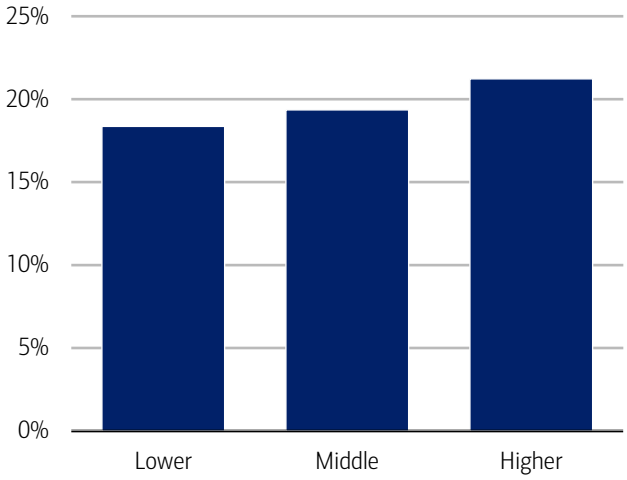

Exhibit 15: Lower-income households have seen larger adoption of BNPL...

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

The differences between the total and per household card spending growth rate (if discussed) can be explained by the following reasons:

1. Overall total card spending growth is partially boosted by the growth in the number of active cardholders in our sample. This could be due to an increasing customer base or inactive customers using their cards more frequently.
2. Per household card spending growth only looks at households that complete at least five transactions with Bank of America cards in the month. Per household spending growth isolates impacts from a changing sample size, which could be unrelated to underlying economic momentum, and potential spending volatility from less active users.
3. Overall total card spending includes small business card spending while per household card spending does not.
4. Differences due to using processing dates (total card spending) versus transaction date (per household card spending).
5. Other differences including household formations due to young adults moving in and out of their parent's houses during COVID.

Any household consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level. Whenever median household savings and checking balances are quoted, the data is based on a fixed cohort of households that had a consumer deposit account (checking and/or savings account) for all months from January 2019 through the most current month of data shown.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards are excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

Store category aggregation for "more discretionary", "partly discretionary", and "mostly necessity" is defined as follows:

More discretionary: furniture, electronics, building materials, hobbies, miscellaneous stores, nonstore retail, clothing.

Partly discretionary: auto, health and personal care, general merchandise.

Mostly necessity: Gasoline, food and beverage.

We consider a measure of services necessity spending that includes but is not limited to groceries, utilities, and gasoline. Discretionary services includes but is not limited to charitable donations, leisure travel, entertainment, and professional/consumer services. Discretionary retail includes but is not limited to general merchandise, miscellaneous, clothing, electronics and furniture. It excludes categories like groceries and gasoline. Holiday spending is defined as items in which spending in the November-December period is usually at least 20% of total annual spending on the category. Value and premium grocers are determined judgmentally on a proprietary analysis of merchants by equity analysts. The "more discretionary" retail category includes furniture, electronics, building materials, online marketplaces, clothing retailers and miscellaneous stores; while "partly discretionary" retail contains auto parts and services, health and personal care retailers, general merchandise and "mostly necessity" retail contains gas and groceries.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Any reference to card spending per household on gasoline includes all purchases at gasoline stations and might include purchases of non-gas items.

Additional information about the methodology used to aggregate the data is available upon request.

BANK OF AMERICA INSTITUTE

BANK OF AMERICA

Economy

The Institute Employment Report: September 2026

07 October 2026

Key takeaways

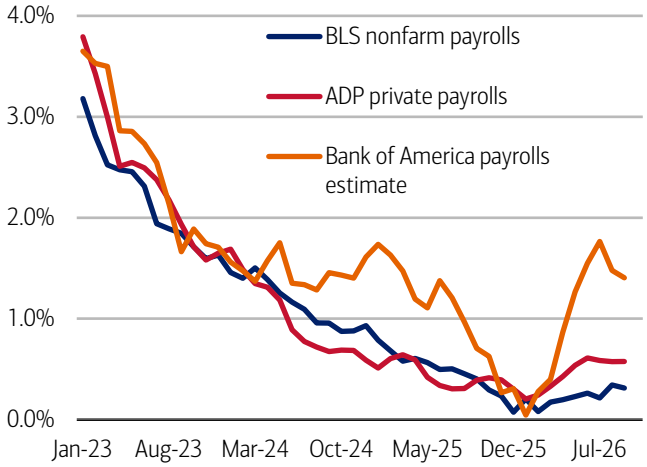

- Job growth softened further in September, according to Bank of America's deposit data, with growth of 1.4% year-over-year (YoY), from 1.5% in August. But falling unemployment payments in September indicate a relatively healthy overall picture.
- Lower-income households' wage growth remains strongest, despite a narrowing gap. After-tax wage growth eased to 4.5% YoY for lower-income households in September, while rising to 3.8% and 3.7% for middle- and higher-income households, respectively.
- Lower tax withholdings and a relative strengthening in the younger/lower-income end of the labor market are driving this story. Additionally, average hours have risen in some lower-paid industries, which is also boosting pay packets.

Job growth slowed in September, but unemployment trends are benign

Our estimate of job growth – which uses Bank of America deposit data to track changes in the number of customer accounts receiving a paycheck (see Methodology) – slowed further in September, to 1.4% year-over-year (YoY) from 1.5% YoY in August. The data can be noisy, partly due to seasonal variation and differences in pay-period timing, but in our view, the latest reading is consistent with the easing in payrolls growth seen in the September Bureau of Labor Statistics (BLS) data (Exhibit 1).

Still, despite slower hiring, there is little sign of a rise in joblessness in Bank of America data. Unemployment payments into customer accounts showed a YoY decline in September (Exhibit 2). So, overall, labor market trends appear resilient.

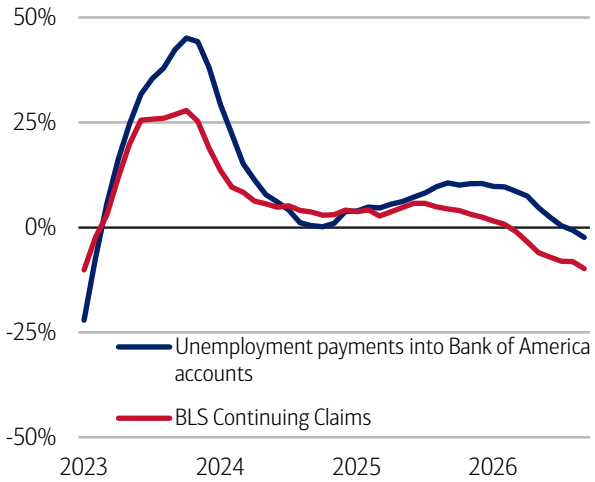

Exhibit 1: September payroll growth showed further slowing in Bank of America deposit account data

BANK OF AMERICA INSTITUTE

After-tax wage growth cooled for lower-income, but rose for other cohorts

Lower-income wage growth eased to 4.5% YoY in September from 4.7% YoY in August, while wage growth for middle- and higher-income households rose to 3.8% and 3.7% YoY, respectively. Overall, these changes were modest, and lower-income households are continuing to see faster after-tax wage growth than other cohorts, a notable turnaround from the "K-shaped" pattern we observed over much of 2025 and 2026 (Exhibit 3).

Exhibit 3: Lower-income wage growth remains strongest, despite a narrowing gap

After-tax wage and salary growth by household income terciles, based on Bank of America aggregated consumer deposit account data (three-month moving average, YoY%, SA)

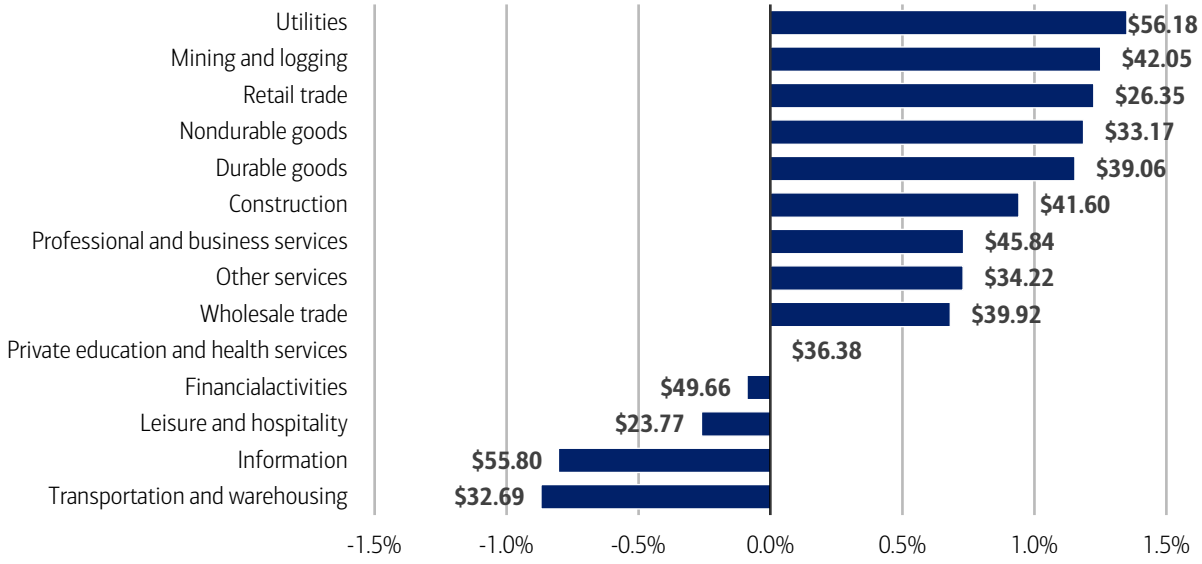

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

In our view, the pick-up in lower- and middle-income households' after-tax wage growth continues to reflect the impact of the One Big Beautiful Bill Act (OBBA) in reducing tax withholdings, alongside an underlying rise in job-to-job changes at the younger/lower-income end of the labor market (for more, read: The Institute Employment Report: August 2026). Consistent with that underlying pick up, BLS data shows a solid YoY rise in average hours worked in several relatively lower-paid industries, such as manufacturing, retail and other services. Hourly workers in these industries are likely seeing rising paychecks as a result (Exhibit 4).

Exhibit 4: Some relatively lower-paid industries have seen a rise in hours worked

Average weekly hours by industry, July-September 2026 (% YoY) and average hourly earnings by industry, July-September 2026 ($)

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards are excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Estimate of payroll growth from Bank of America internal data is based on the change in customer accounts receiving a paycheck in the month. An adjustment is made for the difference between overall population growth and customer account growth. Occasionally historic payments can be reclassified, leading to revisions in the series.

An estimate of bonus growth from Bank of America deposit data is calculated by looking at customers who have received an inbound ACH payroll transaction in the last two years. From this sample an estimate of bonuses is derived by looking for payroll transactions which are over 50% higher than the median regular payroll payments received by the customer. Of these payments only those that were received around the same time in each of the last two years are selected.

The job-to-job change rate (j2j rate) is defined as the proportion of customers with an identified change in their employer as a proportion of the total number of customers with employment income. We estimate the median pay rise associated with a j2j change using the pay in the first three months of the new job compared to the same three months a year ago.

Additional information about the methodology used to aggregate the data is available upon request.

Economy

Entering the age of the older consumer

01 October 2026

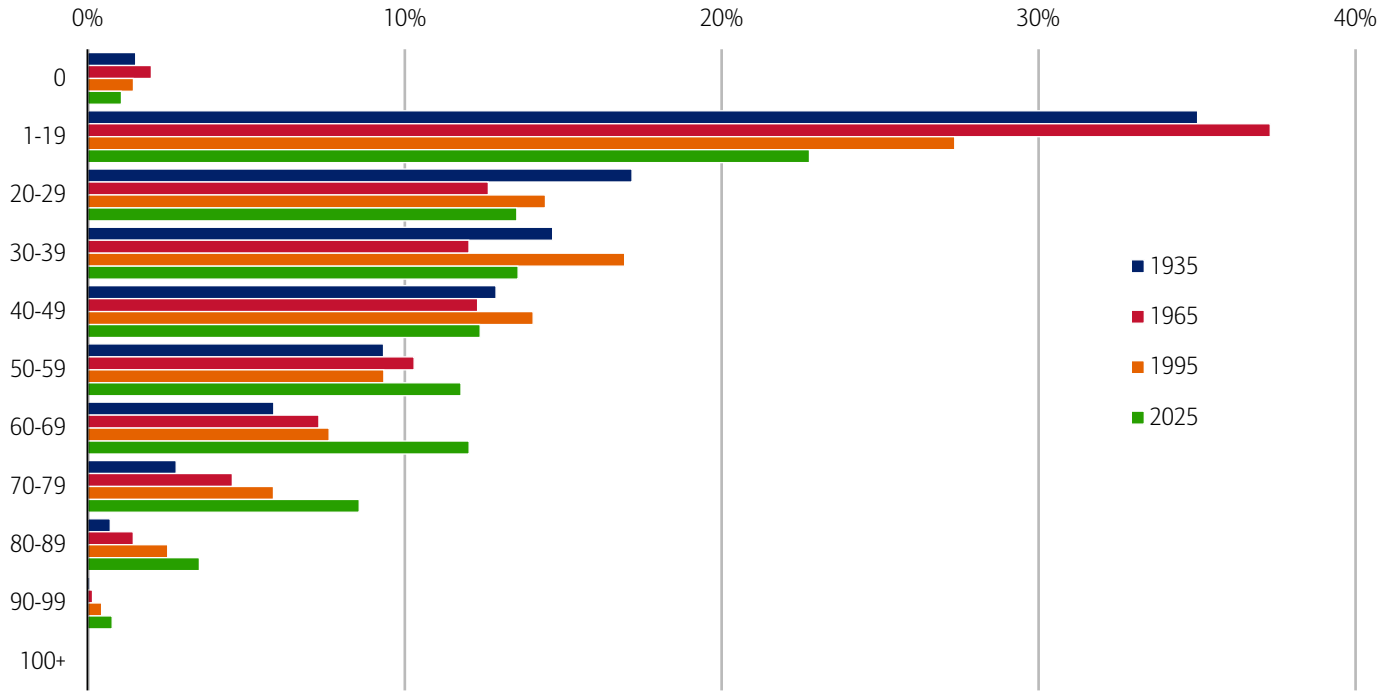

Key takeaways

- The older consumer is moving center stage. America's population has been aging for decades, but the shift has accelerated: the share aged over 60 increased by almost 10 percentage points (pp) between 1995 and 2025. And the Census Bureau projects the share of the population over 60 will rise another 5pp by 2055, to stand at nearly 30% of the population.
- More free time means a different spending mix. People aged 65 and over spend around two and a half fewer hours per day working and roughly two hours more on leisure than the overall adult population. Bank of America data shows that older households allocate relatively more of their card spending to groceries and travel, and less to restaurants, gasoline, general merchandise and clothing.
- Households aged over 55 held close to $140 trillion in net worth in the second quarter of 2026, giving many older consumers considerable capacity to spend on travel and other leisure categories. But wealth is not evenly distributed, and healthcare and other cost pressures remain significant for older households on tighter or fixed incomes.

Population aging is nothing new, but it is accelerating

The US population has been growing relatively "older" for a long time. Exhibit 1 shows that the proportion of the population under 20 years old shrank from the mid-1960s through 2025. At the same time, the proportion of the population in older age groups has been rising.

Exhibit 1: Over time the US population has steadily aged
Proportion of US population by age range (%)

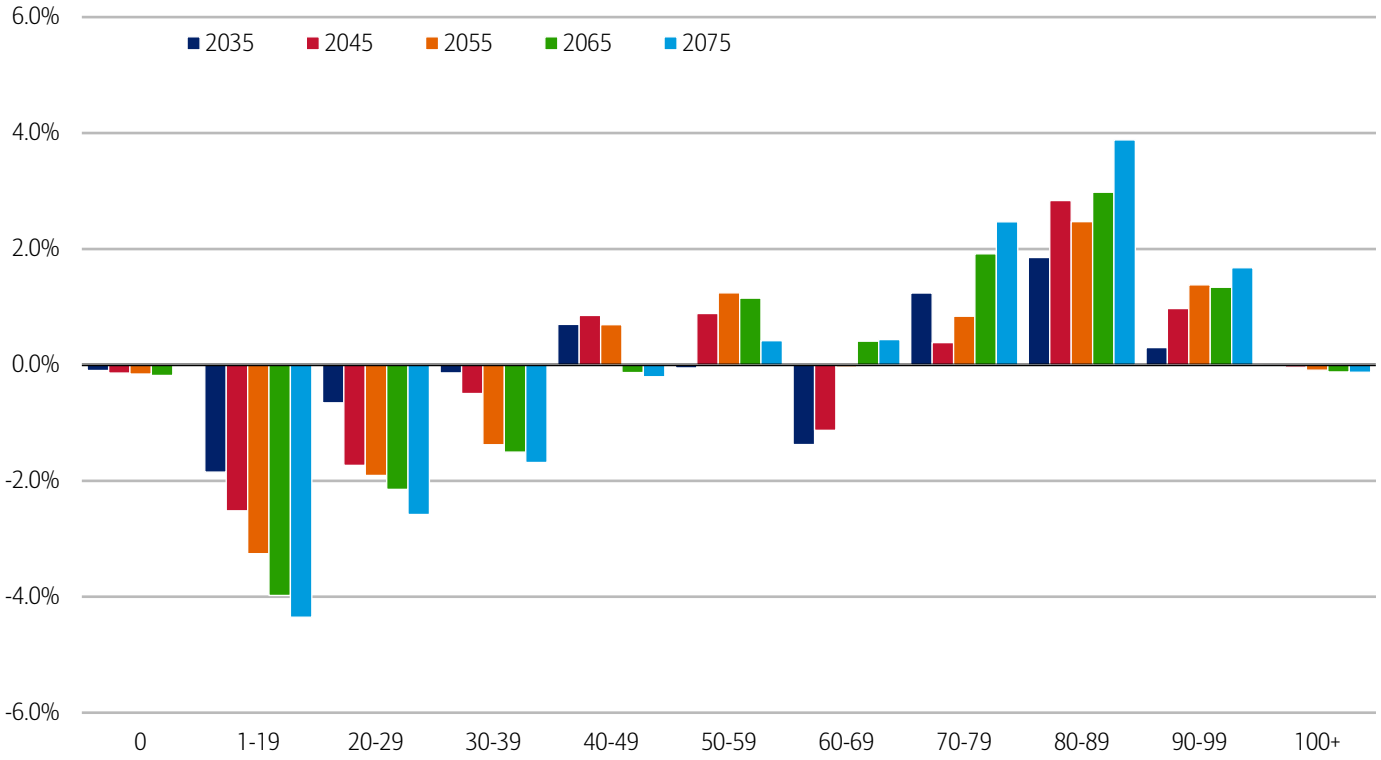

Source: Human Mortality Database; Bank of America Institute calculations

BANK OF AMERICA INSTITUTE

Additionally, there has been a notable acceleration in the relative aging of the population in recent years. For example, between 1995 and 2025, the proportion of the population aged over 60 rose by almost 10 percentage points (pp) to 25%.

Several factors have driven this. First, fertility rates in the US, as in much of the world, have fallen sharply. This has slowed natural population growth and, by reducing the number of younger people relative to older cohorts, has increased the share of the population at older ages. Second, more recently, net inward migration to the US has slowed. Because migrants tend to be younger than the overall population, weaker immigration also tends to raise the average age. Finally, rising life expectancy over much of the post-war period has allowed more people to survive into older age, further increasing the older population's share.

Exhibit 2: The trend towards an older composition of the population is expected to continue
Forecast changes in the share of population by age group relative to 2025 (pp)

Source: United States Census Bureau

BANK OF AMERICA INSTITUTE

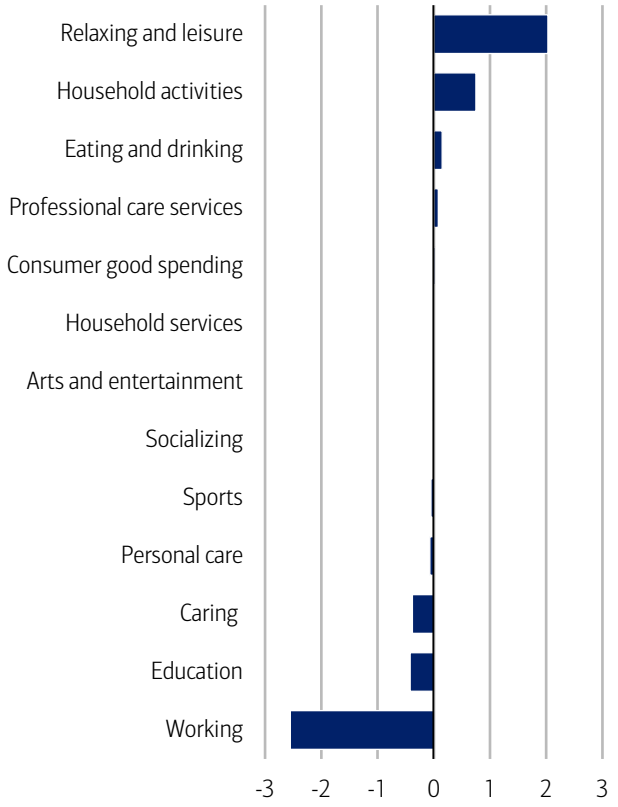

Lower fertility and, more recently, weaker net migration look set to slow overall US population growth in the decades ahead. As a result, older Americans are likely to play an increasingly important role in the economy, both as a share of the population and, in many age groups, in absolute numbers. The Census Bureau projects the share of the population over 60 will rise another 5pp by 2055, to stand at nearly 30% of the population (Exhibit 2). For businesses, understanding how the needs and spending patterns of older consumers differ from those of younger generations will therefore become increasingly relevant.

Older age groups allocate their time differently

Why does this matter? One reason is that older people tend to spend their time and money quite differently from younger adults. Most obviously, many work less or have retired altogether. Data from the American Time Use Survey (ATUS) shows that people aged 65 and over spend, on average, around two and a half fewer hours per day working than the population aged 15+ (Exhibit 3).

That leaves considerably more time for other activities. People aged 65 and over spend around two hours more per day on leisure and sports activities, with television viewing accounting for a particularly large share of this additional leisure time (Exhibit 4).

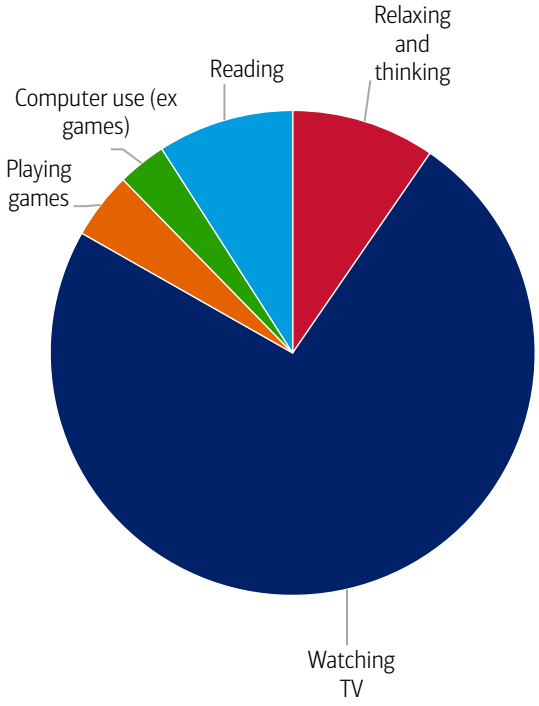

Exhibit 3: Older people spend less time working and more time relaxing
Difference between time spent on activities for those aged over 65 years old compared to all aged over 15 years old (hours)

BANK OF AMERICA INSTITUTE

Older households also spend differently

Bank of America internal data on credit and debit card spending provides insights into how these differences in older generations' use of time also impact their spending. Rather than splitting our spending data by generation, as we often do, here we split by age bands, allowing for consistent comparisons over time.

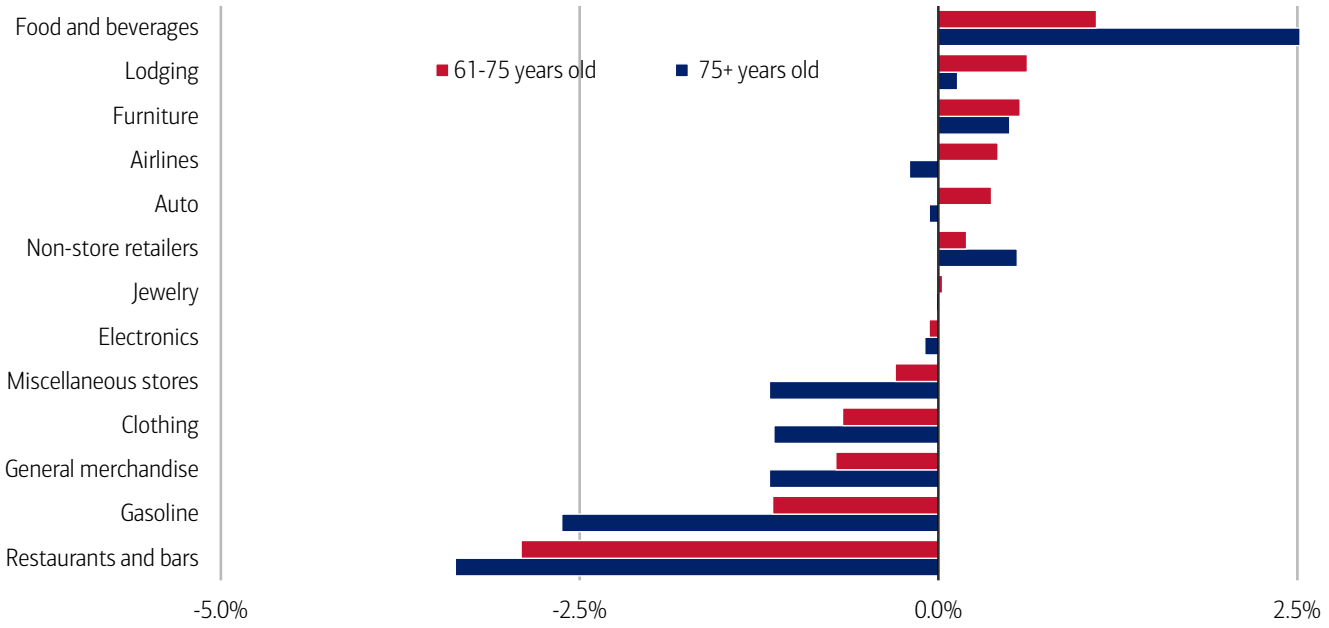

Exhibit 5 shows how the composition of card spending of households aged 61-75 and those older than 75 differs from that of all households. A few things stand out. For one, older households devote a greater share of their overall card spending to groceries (food and beverages). Households aged 61-75 also allocate more spending to travel (airlines and lodging). And restaurants and bars, gasoline, general merchandise and clothing account for a smaller share of older households' card spending.

These differences may seem fairly intuitive. Older households have more leisure hours, so spend relatively more on travel to enjoy them. Previously we found that more available time may support travel particularly around retirement, although the discretionary spending lift can be temporary (for more, read our publication: Paychecks to pensions: The evolution of retiree spending).

Older households are also likely to have less need to update their work wardrobes, so they probably spend less on clothing.

Exhibit 5: Older households allocate more of their card spending to groceries and travel, but less to eating out, gasoline, general merchandise and clothing

Difference in the share of total card spending by households aged 61-75 and 75+ relative to overall households' spending share, by category (January-July 2026, pp)

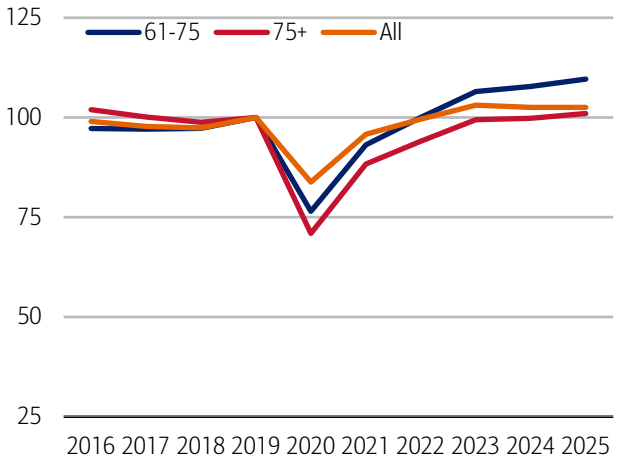

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Still, older households' relatively lower spending on restaurants and bars is a little more curious, perhaps, given dining out could be one way of making use of more leisure time. Indeed, when we look at how these spending shares are evolving, we find a nuanced picture. While households aged 61-75 do spend relatively less on restaurants and bars than the overall population, they appear to be narrowing this gap. But for those older than 75 this is not the case. In our view, the pandemic may still be weighing on dining-out spending among this older age group (Exhibit 6).

Exhibit 6: For restaurants and bars the story is mixed across older cohorts…

Share of households' total card spending on restaurants and bars (annual averages 2016-2025, index 2019 = 100)

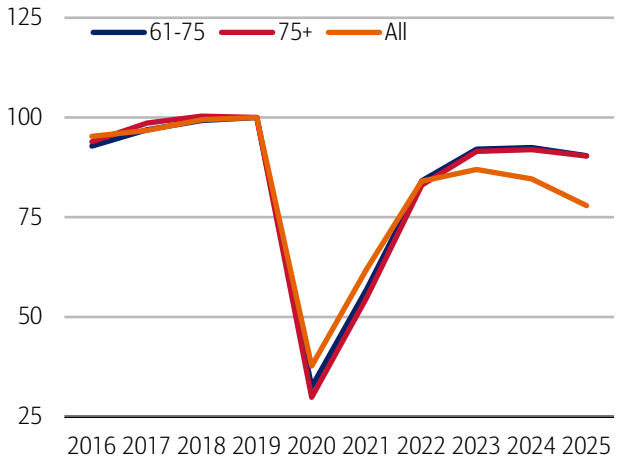

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Exhibit 7: …but they are increasing their spending share relative to the overall population in airlines

Share of households' total card spending on airlines (annual averages 2016-2025, index 2019 = 100)

Source: Bank of America internal data

BANK OF AMERICA INSTITUTE

Interestingly, however, the airline spending share of both older groups has recovered more strongly since the pandemic than that of all households, although it remains below its 2019 level (Exhibit 7).

Aging presents opportunities, but also challenges

In our view, the aging of the US population presents important opportunities for the economy and businesses. Older consumers have more leisure time and businesses that cater to these demands may therefore benefit.

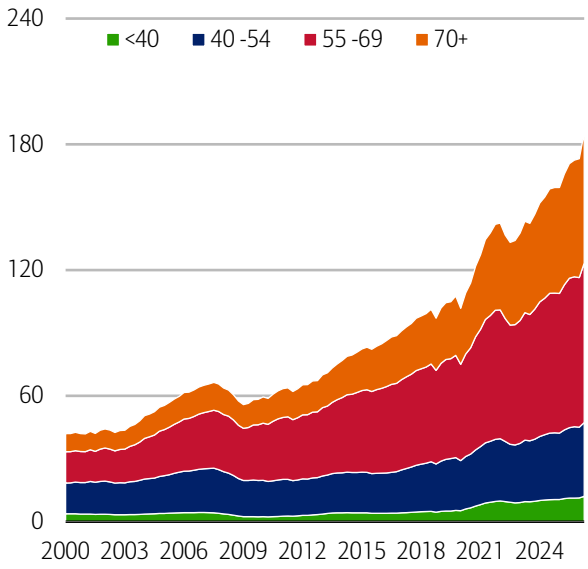

Moreover, some older consumers hold considerable amounts of net wealth and have been some of the biggest beneficiaries of recent rises in equities. Using data from the Federal Reserve, Exhibit 8 shows that as of the second quarter of 2026 the net worth of those households aged 55 and over was close to $140 trillion, around three-quarters of the total. And with equity markets rising strongly, these age groups have seen a more than 20% increase in their net worth over the past two years, potentially enhancing their spending power further.

But an important caveat is that not all older consumers are in this position. Previous Institute work found evidence consistent with equity-market wealth effects being concentrated toward higher-income households (read our publication: Paychecks to pensions: The evolution of retiree spending). And Census Bureau research has found that around 14% of Social Security recipients aged over 65 rely on it for over 90% of their income. For older households without a wealth cushion, recent elevated cost pressures, like gasoline, will likely have put them under more significant financial strain. They will also be more dependent on cost-of-living (COLA) increases in Social Security to underpin their spending.

And, more broadly, outside of card spending, healthcare costs are a much larger factor in older households' budgets (Exhibit 9). The evolution of these costs going forward will be a key variable for older consumers' budgets.

Methodology

Selected Bank of America transaction data is used to inform the macroeconomic views expressed in this report and should be considered in the context of other economic indicators and publicly available information. In certain instances, the data may provide directional and/or predictive value. The data used is not comprehensive; it is based on **aggregated and anonymized** selections of Bank of America data and may reflect a degree of selection bias and limitations on the data available.

Any payments data represents aggregated spend from US Retail, Preferred, Small Business and Wealth Management clients with a deposit account or credit card. Aggregated spend include total credit card, debit card, ACH, wires, bill pay, business/peer-to-peer, cash, and checks.

Any **Small Business** payments data represents aggregate spend from Small Business clients with a deposit account or a Small Business credit card. Payroll payments data include channels such as ACH (automated clearing house), bill pay, checks and wire. Bank of America per Small Business client data represents activity spending from active Small Business clients with a deposit account or a Small Business credit card and at least one transaction in each month. Small businesses in this report include business clients within Bank of America and generally defined as under $5mm in annual sales revenue.

Unless otherwise stated, data is not adjusted for seasonality, processing days or portfolio changes, and may be subject to periodic revisions.

The differences between the total and per household card spending growth rate (if discussed) can be explained by the following reasons:

1. Overall total card spending growth is partially boosted by the growth in the number of active cardholders in our sample. This could be due to an increasing customer base or inactive customers using their cards more frequently.
2. Per household card spending growth only looks at households that complete at least five transactions with Bank of America cards in the month. Per household spending growth isolates impacts from a changing sample size, which could be unrelated to underlying economic momentum, and potential spending volatility from less active users.
3. Overall total card spending includes small business card spending while per household card spending does not.
4. Differences due to using processing dates (total card spending) versus transaction date (per household card spending).
5. Other differences including household formations due to young adults moving in and out of their parent's houses during COVID.

Any household consumer deposit data based on Bank of America internal data is derived by anonymizing and aggregating data from Bank of America consumer deposit accounts in the US and analyzing that data at a highly aggregated level. Whenever median household savings and checking balances are quoted, the data is based on a fixed cohort of households that had a consumer deposit account (checking and/or savings account) for all months from January 2019 through the most current month of data shown.

Bank of America aggregated credit/debit card spending per household includes spending from active US households only. Only consumer card holders making a minimum of five transactions a month are included in the dataset. Spending from corporate cards are excluded. Data regarding merchants who receive payments are identified and classified by the Merchant Categorization Code (MCC) defined by financial services companies. The data are mapped using proprietary methods from the MCCs to the North American Industry Classification System (NAICS), which is also used by the Census Bureau, in order to classify spending data by subsector. Spending data may also be classified by other proprietary methods not using MCCs.

We consider a measure of services necessity spending that includes but is not limited to groceries, utilities, and gasoline. Discretionary services includes but is not limited to charitable donations, leisure travel, entertainment, and professional/consumer services. Discretionary retail includes but is not limited to general merchandise, miscellaneous, clothing, electronics and furniture. It excludes categories like groceries and gasoline. Holiday spending is defined as items in which spending in the November-December period is usually at least 20% of total annual spending on the category. Value and premium grocers are determined judgmentally on a proprietary analysis of merchants by equity analysts.

Durables spending is defined as spending on electronics, building materials, auto-related spending and furniture. Premium durables spending is based on a selection of retailers who are judged to sell relatively higher value products. Conversely, value durables spending is based on a selection of retailers who are judged to sell relatively lower value products.

Lower, middle and higher household income cuts in Bank of America credit and debit card spending per household, and consumer deposit account data are based on quantitative estimates of each households' income. These quantitative estimates are bucketed according to terciles, with a third of households placed in each tercile periodically. The lowest tercile represents 'lower income', the middle tercile represents 'middle income' and the highest tercile 'higher income'. The income thresholds between these terciles will move over time, reflecting any number of factors that impact income, including general wage inflation, changes in social security payments and individual households' income. The income and tercile in which a household is categorised are periodically re-assessed.

Generations, if discussed, are defined as follows: Gen Z, born after 1995; Younger Millennials: born between 1989-1995; Older Millennials: born between 1978-1988; Gen Xers: born between 1965-1977; Baby Boomer: 1946-1964; Traditionalists: pre-1946.

Any reference to card spending per household on gasoline includes all purchases at gasoline stations and might include purchases of non-gas items.

Additional information about the methodology used to aggregate the data is available upon request.

Transformation

Quantum dictionary, part 1: Decoding the fundamentals

21 October 2026

Key takeaways

- What is quantum computing? How does it work? What is a qubit? And when will quantum reach its full potential? Quantum computing challenges our intuition and our understanding of what computers can do. In this two-part dictionary series, we decode key terms behind what could be the next major technological revolution.
- Qubits are the basic building blocks of quantum computers, harnessing properties such as superposition and entanglement to process information. However, qubits are highly sensitive to their surroundings where disturbances can lead to errors in quantum computation, making error correction a key challenge for building quantum computers.
- There is no single approach to building a quantum computer. Researchers and companies are pursuing a range of qubit technologies, from neutral atoms and photons to spin, superconducting, topological and trapped-ion qubits, while quantum computing itself is likely to increasingly work alongside classical computing and AI.

First, let's lay the groundwork...

Quantum computing

Quantum computing uses qubits and quantum properties such as superposition (defined later on) to perform complex calculations and solve certain problems faster than classical computers.[1] From a practical perspective, quantum computing could be used to tackle problems related to optimization, machine learning, simulation and factorization across a range of sectors, including autos and logistics, financial services, energy and climate, health and life sciences and national security.

Current quantum computers can perform 'just' thousands of quantum operations. As the technology advances from thousands to millions, billions and eventually trillions of operations, quantum computers could begin to have commercial applications.

- Millions: Financial services and security could experience some of the first use cases, such as threat detection, fraud prevention, derivatives pricing, bond trading and arbitrage.
- Billions: Quantum could help power AI through advanced data generation capabilities.
- Trillions: Quantum chemistry applications could emerge, including drug discovery, battery simulation and materials discovery.

These are the publicly known applications, according to Oxford Quantum Circuits (OQC). And as quantum computing capabilities improve, some of these use cases could emerge sooner than anticipated.

Now, we'll tackle the core concepts...

Qubits

Qubits (quantum bits) are a quantum computer's basic unit of information. They can exhibit quantum properties such as superposition and entanglement (which we elaborate on below) — properties fundamental to quantum computing.

Quantum gates manipulate the state of qubits, much like logic gates manipulate bits in classical computers. Despite the name, a quantum gate is not a physical object, but rather an operation applied to a quantum system that changes its state.

From physical to logical qubits

Physical qubits are the foundation of a quantum computer's hardware. However, they are highly susceptible to error. To address this, multiple physical qubits can be structured together to encode a logical qubit, allowing errors to be detected and corrected

[1] Schneider, J., & Smalley, I. (2025, June 10). *What is quantum computing?* IBM.

and making the stored quantum information more reliable. In recent years, according to BofA Global Research, logical qubits have become a greater focus for quantum computing companies.

Entanglement

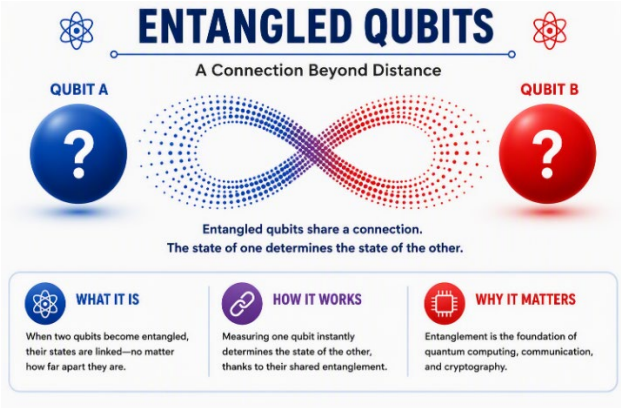

Entanglement is a condition where two or more qubits become linked so that their states are correlated, regardless of distance (Exhibit 1). It allows quantum computers to process information in ways that can be difficult or impossible for classical computers.

So, how does it work? Suppose we have two photons that have opposite polarizations (the orientation of their light waves). Before measurement, neither has a definite polarization. When one is measured as horizontally polarized, the other will be vertically polarized when measured in the same basis, wherever it is. When measured separately, they appear to be random, but when compared, they are correlated (Exhibit 2).

The challenges

Once created, entanglement must be protected from decoherence (where interactions with the environment destroy quantum correlations). Maintaining entanglement over long distances is another challenge. Photons traveling through optical fiber can be absorbed or scattered, making long-distance quantum communication difficult.[2] Quantum repeaters aim to overcome this challenge by extending entanglement across a series of shorter links.

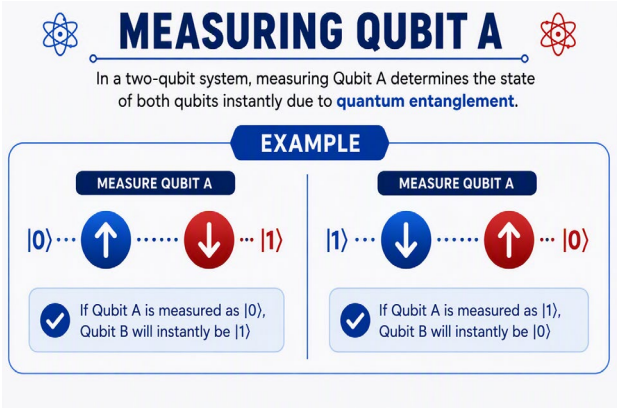

Exhibit 1: Entanglement is a state where at least two qubits become correlated
An infographic of entangled qubits

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

Exhibit 2: Measuring one qubit in an entangled pair instantly determines the state of the other, no matter the distance
An example of what entanglement means for qubit measurement

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

Superposition

Unlike a classical bit, which can be one of two states (0 or 1), superposition allows a quantum system to exist in multiple states or configurations at the same time (Exhibit 3). For example, a qubit can exist in the 0 state, the 1 state or any state that is a combination of 0 and 1.[3]

A quantum system can maintain a superposition until it is observed or measured. Once measured, its superposition collapses into a single state. Another way of thinking about superposition is to imagine a sphere with the north pole representing zero and the south pole representing one. Other points on the surface of the sphere represent different superposition states. This allows us to: 1) represent complex forms of information; and 2) simulate atoms in a computer.

Schrödinger's cat

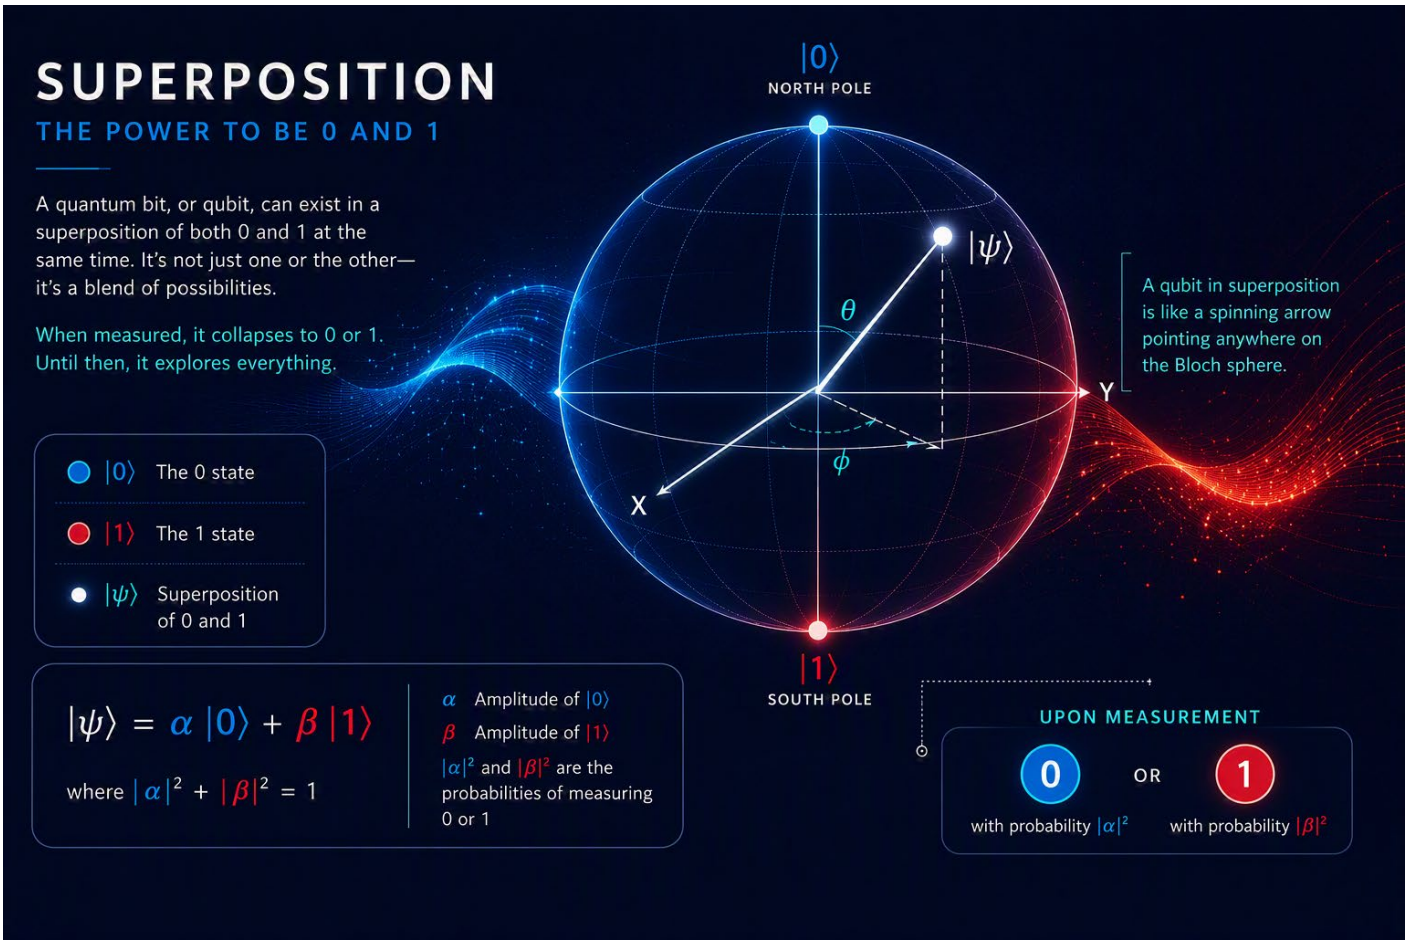

In 1935, physicist Erwin Schrödinger proposed a thought experiment to illustrate the strange implications of quantum mechanics. In this scenario, a cat, a radioactive substance that decays very slowly, and a Geiger counter are put together in a sealed box. According to quantum mechanics, the system can be described as a superposition in which the cat is both alive and dead until the box is opened. Once the box is opened and the system is observed, the superposition collapses into a single outcome.

[2] Rehman, M. (2026, May 11). *What is Quantum Entanglement?* Quantum Insider.
[3] Microsoft. (n.d.). *Superposition.*

Enabling parallel computation versus classical computing

Superposition is a key attribute of quantum computing that allows for quantum parallelism, or the ability to perform multiple computations at the same time. Classical bits can only be in one of two states, 0 or 1. In contrast, a qubit can be in a superposition of 0 and 1, allowing a quantum computer to process multiple possible qubit states at once.[4]

Exhibit 3: Superposition is the condition where a qubit can exist in a superposition of 0 and 1
Illustrating the power of superposition

Note: A Bloch sphere is a geometric representation of qubit states.

BANK OF AMERICA INSTITUTE

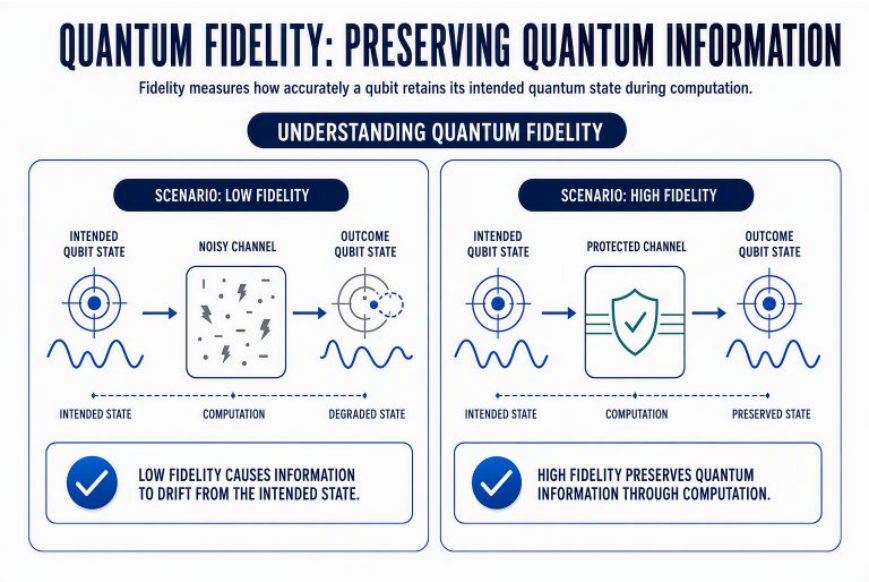

Error rates and fidelity

Fidelity is a measure of how closely a quantum state or operation matches what was intended (Exhibit 4). A higher fidelity generally means fewer errors.

Physical qubits are prone to errors. One way to address this is to combine multiple physical qubits to create a more reliable logical qubit. Quantum error correction (QEC) allows errors in the physical qubits to be detected and corrected, helping protect the information stored in the logical qubit.

[4] Ibid.

Exhibit 4: Fidelity measures how accurately a qubit retains its intended quantum state during computation
Infographic showing the implications of high versus low fidelity

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

How does quantum error correction work?

At its simplest, QEC relies on redundancy, or storing information across multiple qubits so that errors can be detected and corrected**.**

Consider an example: suppose someone wants to send a message represented by 0. Instead of sending a single 0, the message could be repeated three times as 000, known as a codeword. If one bit were accidentally flipped from 0 to 1 during transmission, the recipient might receive 010. Because two of the three bits are still 0, the recipient could infer that the intended message was 000.

However, if two bits flipped, producing 110 or 011, the recipient could infer the wrong message. If all three flipped to 111, the recipient would have no way to know from the received codeword that errors had occurred.[5] This approach is known as a repetition code and illustrates how redundancy can help protect information from errors.

Repetition codes are a simple form of error correction that can address bit-flip errors, where a 0 changes to a 1 or vice versa. More sophisticated QEC codes are needed to address other quantum errors, such as phase flips.[6] Shor's code, developed by American theoretical computer scientist Peter Shor, uses nine physical qubits to encode one logical qubit and can correct one bit-flip error or one phase flip error, but it can't correct both types of errors at the same time. Meanwhile, Steane's seven-qubit code, developed by Oxford physicist Andrew Steane, can also correct both types of errors. It has the advantage of being fault-tolerant, meaning the error-correction process itself does not introduce additional errors.[7]

At what error level might we start seeing quantum advantage?

Some classical computing systems today operate with extremely high reliability, often described as having "17 nines" of fidelity (99.99999999999999%). By comparison, quantum computers currently achieve fidelity rates of around 99.9%. Gerald Mullally, CEO of OQC, has argued that quantum systems would need to add roughly three more nines of fidelity to achieve commercial relevance, or quantum advantage.

Noise and decoherence

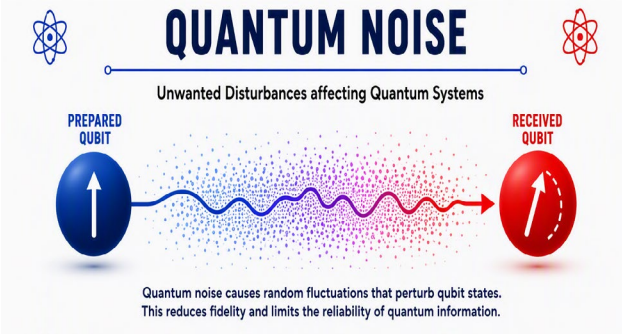

Noise refers to unwanted disturbances that affect quantum systems and can lead to errors in computations (Exhibit 5). It can come from sources such as interactions with the environment, electromagnetic interference and temperature fluctuations. Coherence is a quantum system's ability to maintain its quantum properties, including superposition and entanglement. When coherence is lost through interactions with the environment, the process is known as "decoherence," causing the system to behave more classically (Exhibit 6).[8]

[5] Microsoft Ignite. (n.d.) *Introduction to quantum error correction.*
[6] Ibid.
[7] Ibid.
[8] Quandela. (n.d.) *Quantum Decoherence.*

To fully control qubits for calculations and information transfer, they need to be carefully protected from their surroundings. External factors like noise, energy, changes in Earth's magnetic field, radiation from Wi-Fi or mobile phones or cosmic rays can interfere with the process. Even small disturbances can lead to decoherence, making it difficult to develop large-scale, fault-tolerant quantum computers.[9]

According to QuEra Computing, quantum noise can be mitigated through physical isolation of qubits, the development of more precise control techniques and quantum error correction, which helps detect and correct errors in physical qubits.

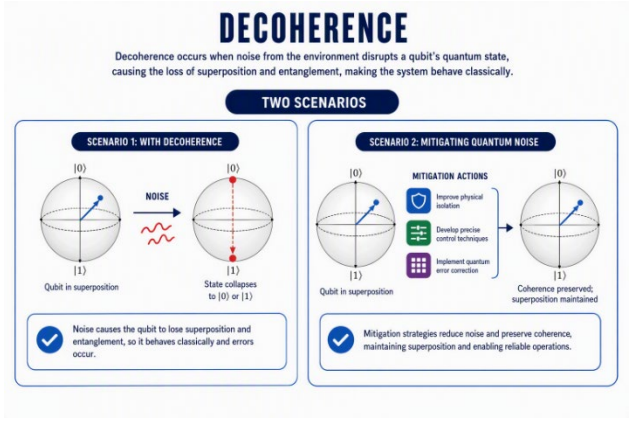

Exhibit 5: Noise refers to unwanted disturbances, e.g., interactions with the environment, that lead to errors in quantum computation

BANK OF AMERICA INSTITUTE

Quantum processing unit (QPU)

Referred to as the brain of the quantum computer, the QPU is the core hardware where qubits reside and where quantum computations take place. QPUs rely on quantum behaviors like superposition and entanglement to tackle problems in areas such as cryptography, simulation and optimization. Just as a CPU (central processing unit) in classical computing contains multiple components, a QPU includes quantum gates (operations that manipulate qubits in a controlled way, similar to logic gates in classical computing) and interconnects, which enable communication between qubits and other quantum processors.[10]

Next, we'll look at broader computing architecture...

Heterogeneous computing

Heterogeneous computing refers to a future computing landscape likely combining classical and quantum computing, potentially unlocking more powerful, faster and cheaper compute and helping solve problems that classical computers cannot. According to BofA Global Research, AI and quantum computing could also converge and complement each other, enabling more transformative use cases.

Quantum modality

A quantum modality refers to the type of physical technology used to create and manipulate qubits. We discuss the modalities in greater depth in the following section.

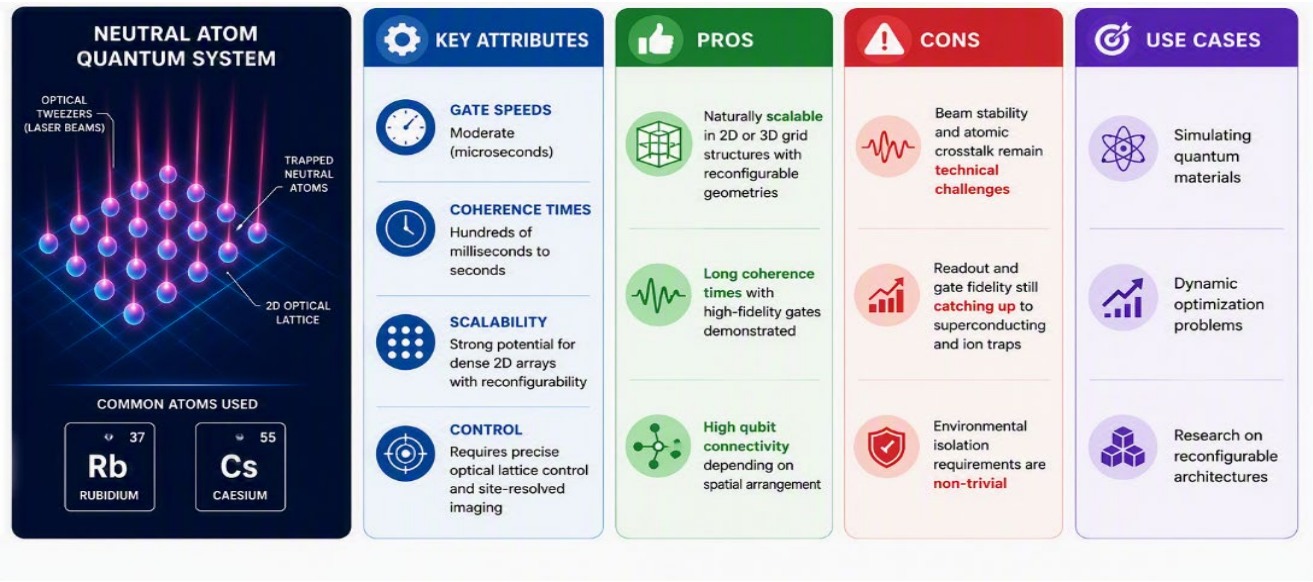

Lastly, we outline qubit technologies...

Neutral atom qubit

A quantum modality that uses individual atoms with no electrical charge as qubits (Exhibit 7). The atoms are held in place using focused lasers known as optical tweezers. Neutral atom qubit systems do not require atoms to be ionized, which means fewer energy constraints and potentially simpler cooling requirements. Atoms such as rubidium or cesium are typically used. The qubits are manipulated by changing the energy levels or positions of the trapped atoms using laser pulses.

[9] QuEra. (n.d.) *Quantum Noise.*
[10] SpinQ. (2025, January 16). *What does a Quantum Computer Look Like? Explain Key Parts.*

Exhibit 7: A quantum modality where atoms with a net electrical charge of zero are the foundation for qubits
Key features of neutral atoms

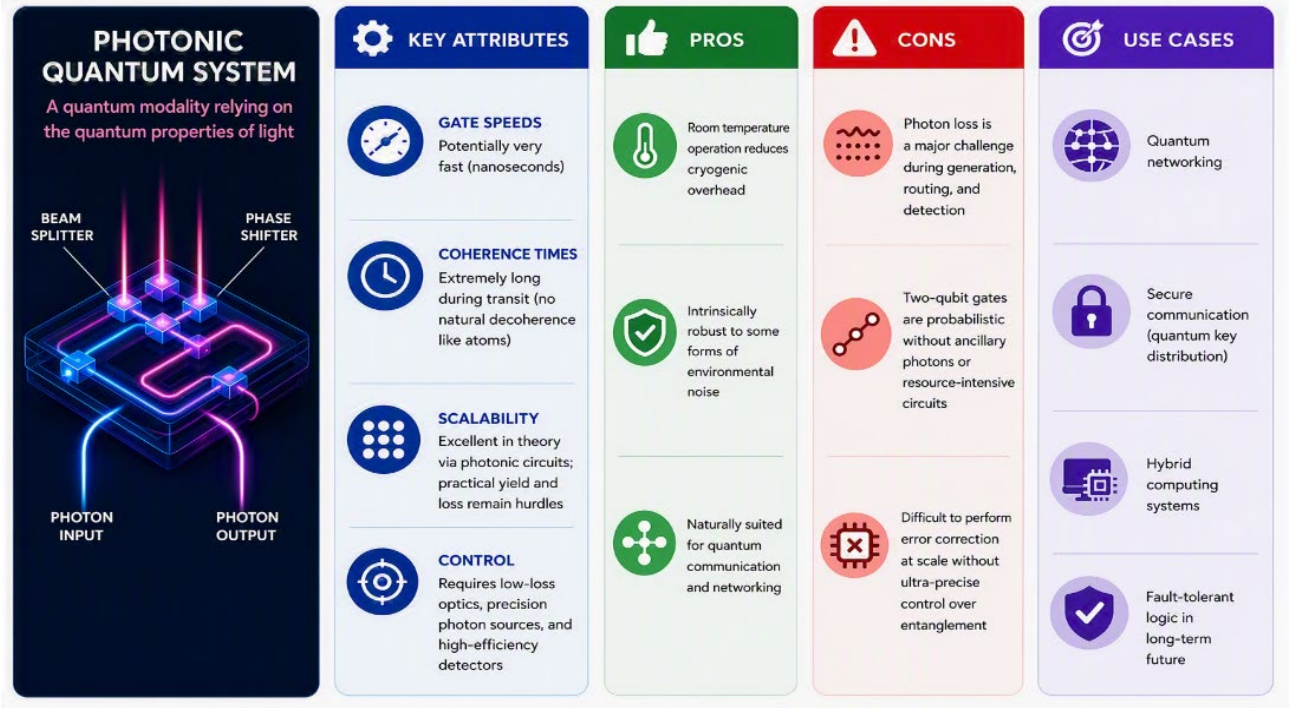

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

Photonic qubit

A quantum modality that uses particles of light, known as photons, to carry quantum information (Exhibit 8).[11] Optical components such as beam splitters, which divide light along different paths, and phase shifters, which change the phase of light, can be used to perform quantum operations. Photonic quantum computers can use integrated photonic chips to manipulate photons and enable quantum logic.

Exhibit 8: A quantum modality relying on the quantum properties of light
Key features of photonic qubits

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

[11] Moore, J. (2025, March 28). *The 6 different types of quantum computing technology*. TechTarget.

Spin qubit

A quantum modality that uses the intrinsic spin of electrons or nuclei in solid-state materials, such as silicon or diamond. These spins can be manipulated using magnetic or electric fields, and their states are read using optical or charge-sensing techniques. Spin qubits are particularly appealing because they can leverage existing CMOS (complementary metal-oxide semiconductor; a technology to build processors) manufacturing infrastructure, making it easier to integrate them with conventional processors.

Superconducting qubit

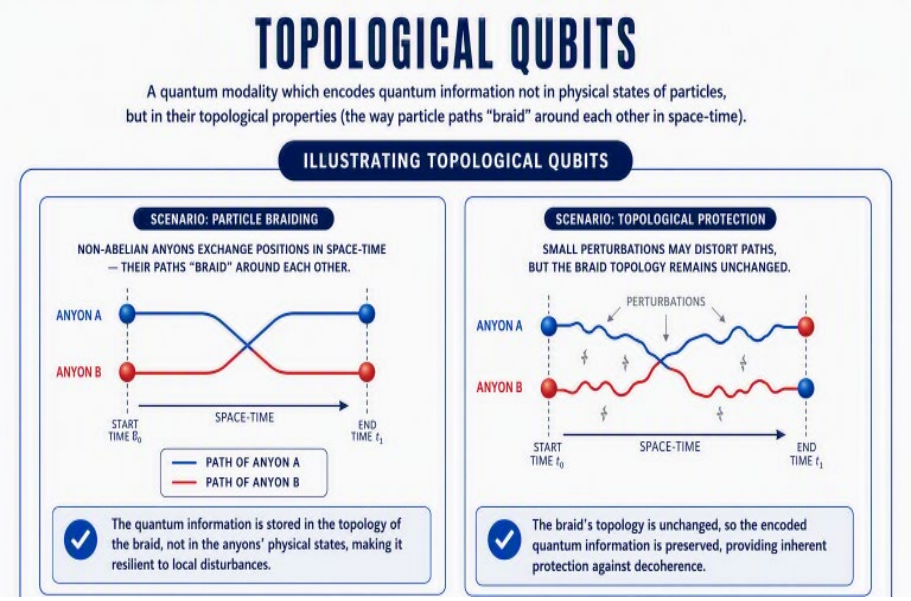

A quantum modality in which electronic circuits create qubits. They are built using Josephson junctions, where two superconductors are separated by a thin insulating layer. Microwave pulses manipulate the qubits' quantum states to run computations.[12]

Specifically, a resistance-free current oscillates back and forth around a quantum loop. An injected microwave signal excites the current into superposition states.[13] To enable this process, superconducting materials are cooled to near absolute zero (around 10-20 millikelvin) using dilution refrigerators, helping reduce thermal noise and maintain coherence.

Topological qubit

A quantum modality that aims to encode quantum information using topological properties rather than relying only on individual particle states (Exhibit 9). One way to think about this is through the paths certain quasiparticles take as they move around one another, creating "braids" in space-time. Because the information can depend on the overall pattern of these braids rather than small details of their paths, the approach is designed to be more resilient to certain disturbances.

Exhibit 9: Resilient to small perturbations but requires special quasiparticles not yet been conclusively demonstrated in nature
An infographic of topological qubits

Source: BofA Global Research

BANK OF AMERICA INSTITUTE

Trapped-ion qubit

A quantum modality in which ions (electrically charged atoms) are held in place using electromagnetic fields. These ions act as the qubits and are controlled by the system with tightly focused laser beams.[14] The qubits are held inside ultra-high vacuum (UHV) chambers.
